times when this part of the territory of North America was discovered, there has existed at the mouth of the Chicago River a trading post; that from 1778, a fort, afterwards known as Fort Dearborn, was situated near the mouth of said river and on the south side thereof; that the said Fort and other buildings were practically destroyed in the Massacre of 1812; that the said Fort Dearborn was rebuilt by the United States in the year 1816; that during the early days the sewage of said Fort and the houses adjoining thereto was disposed of by cesspools and by other methods customarily used in small urban communities; that in the year 1837, the Village of Chicago was organized with 709 lawful voters; that between said year 1837 and the year 1854 when the City of Chicago was incorporated, the Village had grown with very rapid strides so that there [fol. 120] was a population of approximately 40,000 people in the City of Chicago in the year 1854; that by reason of the natural conditions which existed at Chicago as set out in detail hereinbefore, to-wit: the location of said City on a flat, low, marshy and sandy soil with only a slight elevation above the level of Lake Michigan, said City was confronted at that early day with the necessity of constructing a sewer system and was obliged to and did raise the level of its streets so as to permit the construction therein of a sewer system, and entered thereupon, upon the systematic construction and development of such a sewer system; that between the years 1854 and the year 1889 sewers were constructed in the territory of said City of Chicago north of the Chicago River, which drained into the Chicago River as far north as the boundaries of said City of Chicago; that the territory lying to the west of both the North Branch and the South Branch of the Chicago River constructed sewers draining into the Chicago River; that the territory lying south of the Chicago River and east of State Street constructed sewers draining into Lake Michigan; that is to say, said territory constructed sewers at 12th Street, 22nd Street and in 31st Street emptying directly into Lake Michigan; that the territory above described as being within the boundaries of the City of Chicago as it existed in 1889 was bounded on the north by Fullerton Avenue, at a distance of 2½ miles north of the Chicago River, on the west by Western Avenue at a distance of between 4 and 5 miles west of Lake Michigan, and on the south by 39th street, a distance of approximately 4½ miles south of the mouth of the Chicago River.

22. This defendant states that south of 39th Street and adjoining thereto was situated the flourishing village of Hyde Park with a population in 1889 of 41,000, the largest part of which had sewers emptying directly into Lake Michigan; that west of said village of Hyde Park was situated a town of considerable size known as the [fol. 121] Town of Lake, with a population of, to-wit: 58,661; that the sewage from said Town of Lake emptied into the South Fork of the Chicago River; that situated north of Fullerton Avenue, being the northern boundary of said City of Chicago was situated the Town of Lake View with a population of , to-wit: 42,339, which had several sewers emptying into Lake Michigan; that situated west of said

Town of Lake View was situated the Town of Jefferson, whose sewers emptied into the North Branch of the Chicago River, with a population in 1889 of, to-wit: 10,662; that the population of the City of Chicago in 1889 was, to-wit, 802,651; that by reason of the fact that the said City of Chicago and the towns of Lake View and Hyde Park emptied their sewage directly in to Lake Michigan, and that other portions of said City of Chicago, said Town of Jefferson and said Town of Lake emptied their sewage into the Chicago River, which in turn during portions of the year discharged itself into Lake Michigan, the said water of the Chicago River and the waters of Lake Michigan adjoining the said City of Chicago became and were badly polluted and the danger to health and condition of nuisance resulting therefrom became so aggravated as to necessitate the creation of this defendant for the purpose of abating the said pollution and nuisance thereby created, and providing a way as hereinafter more fully shown of disposing of the sewage of said City of Chicago and its adjacent towns and villages.

23. This defendant further states that the inhabitants of the Village of Chicago obtained their drinking water from shallow wells sunk into the sand, upon which said Village of Chicago was founded; that the water obtained therefrom consisted of the water of Lake Michigan or of the Chicago River which had seeped through the said sands and into said shallow wells and did not consist of natural underground water; that as the said Village grew in population to a [fol. 122] city, the said shallow wells became badly polluted by sewage and by the drainage water and refuse washed into said wells, and as a result the people of said city became obliged to obtain their water from Lake Michigan; that at first water wagons were employed to cart the water from the lake to the individual users and later a wooden pipe was laid in the streets; that subsequently a tunnel was extended out into Lake Michigan at Chicago Avenue and a crib built at the Lake extremity to prevent the end of said tunnels being injured or choked up by ice in the winter time; that the City of Chicago, and some of the towns or villages mentioned built in Lake Michigan six intakes, cribs and tunnels connected therewith for the purpose of obtaining water from Lake Michigan as follows: The Lake View Crib on the northern extremity of said city at a distance of two miles from the shore of Lake Michigan; the Carter H. Harrison Crib, situated at a distance of three miles from the shore; the Chicago Avenue Crib, situated at a distance of two miles from shore; the Four Mile Crib situated at approximately four miles from the shore and opposite the most densely populated portion of said City of Chicago, and the Hyde Park and Edward F. Dunne Cribs, two miles off shore, situated near the southern extremity of said City; that from each of the said cribs large tunnels extended in the earth under Lake Michigan to points on the shore where pumping stations are erected, by means of which water is pumped through the said tunnels and distributed through distributing pipes or water mains to the people of the City of Chicago, and adjoining towns; that the said distributing system is interconnected so that in case any one

crib or tunnel should be incapacitated, the other tunnels would furnish water to the people who would ordinarily take from that tunnel by means of inter-connecting pipes, but the said City of Chicago has spent in and about the construction of said cribs and water tunnels and in and about the construction of its distributing pipes and distributing tunnels large sums of money, in excess of, to-wit: [fol. 123] $59,042,565.00; and that said City of Chicago has no other means or source from which it could obtain a water supply of the quality and amount adequate to its needs and is therefore obliged to and will be obliged to obtain its entire drinking water supply out of said Lake Michigan.

This defendant shows that by reason of the facts hereinbefore set forth that between the years 1880 and 1900 when this defendant opened its channel, as hereinafter set forth, the said waters of Lake Michigan, from which the inhabitants of the City of Chicago and environs were obliged to obtain their water supply, were badly polluted by reason of the fact that the sewage of said City of Chicago and adjoining towns and villages thereto, as well as the drainage water of a large drainage area was discharged into Lake Michigan.

24. This defendant states that from the earliest discovery of this country, there has existed between Lake Michigan and the Mississippi River a water route used as a highway of trade and travel; that this water route originally consisted of the Chicago River, its south branch and the west fork thereof, a ditch or canal in wet seasons and a portage in dry seasons, from thence into a lake known as Mud Lake, and a ditch or canal in wet seasons and a portage in dry seasons from said Mud Lake into the Desplains River; from thence said route proceeded down the Desplaines River into the Illinois River and thence into the Mississippi River. That the said route was used for the purpose of carrying on trade and for the purpose of travel for upwards of 160 years, and that said use was prior to any improvements made by the United States or by the government then controlling the country now known as Canada.

That there existed also during the said period from the lower end of Lake Michigan through the Great Lakes and its connecting waters to the Atlantic Ocean two water routes, one by way of a portage around Niagara Falls and from thence on the St. Lawrence River [fol. 124] to the Atlantic Ocean; that the other water route consisted of a route through Georgian Bay, Lake Nipissing, and down the Ottawa River into the St. Lawrence River and thence to the Atlantic Ocean; that the said water route hereinbefore described from Lake Michigan into the Mississippi River, and the said two water routes from the lower end of Lake Michigan to the Atlantic Ocean were used for the purpose of trade and for travel prior to the year 1830 and for some time subsequently.

That about the year 1822 there was a great demand for improvement of these water routes; that on or about March 30th, 1822, the Congress of the United States passed an act granting to the State of Illinois certain public lands for the purpose of aiding the State of Illinois in constructing a canal "connecting the Illinois River

with the southern end of Lake Michigan;" that the said act of the Congress of the United States is in the words and figures as follows, to-wit:

Act of March 30, 1822

(3 U. S. Stat. at Large, p. 659)

An Act to Authorise the State of Illinois to Open a Canal Through the Public Lands to Connect the Illinois River with Lake Michigan. (Approved and in force March 30, 1822.)

Section 1. Be it enacted by the Senate and the House of Representatives of the United States of America, in Congress Assembled: That the State of Illinois be, and is hereby authorized to survey and mark, through the public lands of the United States, the route of the canal connecting the Illinois River with the southern bend of Lake Michigan; and ninety feet of land on each side of said canal shall be forever reserved from any sale to be made by the United States, except in the cases hereinafter provided for, and the use thereof forever shall be, and the same is hereby vested in the said State for a canal, and for no other purpose whatever; on condition, however, that if the said State does not survey and direct by law said canal to be opened, and return a complete map thereof to the treas-
[fol. 125] ury department, within three years from and after the passage of this act; or, if the said canal be not completed, suitable for navigation within twelve years thereafter; or, if said ground shall ever cease to be occupied by, and used for, a canal suitable for navigation; the reservation and grant hereby made shall be void and of none effect; Provided, always, and it is hereby enacted and declared, that nothing in this act contained, or that shall be done in pursuance thereof, shall be deemed or construed to imply any obligation on the part of the United States to appropriate any money to defray the expenses of surveying or opening said canal; Provided, also, and it is hereby further enacted and declared, that the said canal, when completed, shall be and forever remain a public highway for the use of the Government of the United States, free from any toll or other charge whatever, for any property of the United States, or persons in their service passing through the same.

(Sections through which the canal passes reserved until, etc.—The state may use necessary adjacent material without waste.)

2. And be it further enacted, That every section of land through which said canal route may pass, shall be, and the same is hereby reserved from future sale, until hereafter specially directed by law; and the said State is hereby authorized and permitted, without waste, to use any materials on the public lands adjacent to said canal, that may be necessary for its construction.

That the said act provided that if the State of Illinois did not make a survey and furnish a complete copy thereof to the Treasury Department within three years from and after the date of its passage, or if

the said canal be not completed suitable for navigation within twelve years thereafter, or if said ground shall ever cease to be occupied and used for a canal suitable for navigation, the reservation and grant made shall be void and of no effect; that the State of Illinois did not within the three year period provided for in the act return a complete map of the canal, and the rights granted under the said act lapsed pursuant to the terms thereof; that subsequently to the passage of the said act and prior to March 2nd, 1827, and subsequently [fol. 126] thereto, the Government of Great Britain refused to the citizens of the United States of America the free navigation of either or both of the water routes hereinbefore described, and particularly the free navigation of the St. Lawrence River; that the United States of America claimed that under the laws of nations the citizens of the United States were entitled to the use of such outlet for the purpose of carrying on trade and for travel.

That on or about the 28th day of January, 1826, a memorial was addressed to the Congress of the United States by the General Assembly of Illinois, which said memorial is attached hereto as Exhibit "F" and made a part hereof. That in and by the said memorial the General Assembly of the State of Illinois represented to the Congress that the construction of a canal "uniting the waters of Lake Michigan with the Illinois River will form an important addition to the great connecting chain of internal navigation."

That the action of the Government of Great Britain in refusing to the citizens of the United States the free navigation of the St. Lawrence River made it necessary for the United States to provide a free and unobstructed water route from the Great Lakes to the Atlantic Ocean by way of the Desplaines, Illinois and Mississippi Rivers and the Gulf of Mexico.

That thereupon on or about the 2nd day of March, 1827, the Congress of the United States passed an act granting to the State of Illinois certain public lands "for the purpose of aiding the State in opening a canal uniting the waters of the Illinois River with those of Lake Michigan." That the said Act of March 2nd, 1827, is in words and figures as follows, to-wit:

[fol. 127] **Act of March 2, 1827**

(4 U. S. Stat. at Large, p. 234)

An act to grant a quantity of land to the State of Illinois for the purpose of aiding in opening a canal to connect the waters of the Illinois River with those of Lake Michigan. (Approved and in force March 2, 1827.)

Section 1. Be it enacted by the Senate and House of Representatives of the United States of America, in Congress Assembled, That there be and hereby is granted to the State of Illinois, for the purpose of aiding the said State in opening a canal to unite the waters of the Illinois River with those of Lake Michigan, a quantity of land equal to one-half of five sections in width, on each side of said canal, and re-

serving each alternate section to the United States, to be selected by the Commissioner of the Land Office, under the direction of the president of the United States, from one end of the said canal to the other; and the said land shall be subject to the disposal of the Legislature of the said State, for the purpose aforesaid, and no other; Provided, That the said canal when completed, shall be and forever remain a public highway for the use of the Government of the United States, free from any toll, or other charge, whatever, for any property of the United States, or persons in their service passing through the same; Provided, That said canal shall be commenced within five years and completed in twenty years, or the State shall be bound to pay to the United States the amount of any lands previously sold, and that the title to purchasers under the State shall be valid.

(Duty of the Governor of the State when the canal is located, etc.)

2. And be it further enacted, That so soon as the route of the said canal shall be located and agreed on by the said State, it shall be the duty of the Governor thereof, or such other person or persons as may have been, or shall hereafter be, authorized to superintend the construction of said canal, to examine and ascertain the particular sections to which said State will be entitled, under the provisions of this act, and report the same to the Secretary of the Treasury of the United States.

[fol. 128] (Powers Given to the Legislature)

3. And be it further enacted, That the said State under the authority of the Legislature thereof, after the selection shall have been so made, shall have power to sell and convey the whole, or any part of the said land, and to give a title in fee simple therefor, to whomsoever shall purchase the whole or any part thereof.

That in and by the said Act of March 2nd, 1827, the Congress provided for the uniting of the waters of Lake Michigan with those of the Illinois River and made possible the establishment of an outlet from Lake Michigan, and thereby brought Chicago and its surrounding territory into the Mississippi River water-shed; that pursuant to the said Act of March 2nd, 1827, the State of Illinois by act of the General Assembly of January 9, 1836, provided for the construction of a canal of a certain depth to be supplied with water from Lake Michigan; that Section 16 of said act of the General Assembly of the State of Illinois of January 9th, 1836, entitled, "An Act for the construction of the Illinois and Michigan Canal," is as follows:

"That said canal shall not be less than forty-five feet wide at the surface, thirty feet at the base, and of sufficient depth to insure navigation of at least four feet, to be suitable for ordinary canal boat navigation, to be supplied with water from Lake Michigan and such other sources as the Canal Commissioners may think proper, and to be constructed in the manner best calculated to promote the permanent interests of the country, reserving ninety feet on each side of

said canal to enlarge its capacity whenever in the opinion of the Board of Canal Commissioners the public good shall require it."

That the plan of the said canal as originally contemplated under the act of the General Assembly of January 9th, 1836, provided for the flow of the waters of Lake Michigan by gravity into and through the canal and from thence into the Illinois River; that the plan originally proposed was known as the deep-cut plan; that on account of lack of funds the State of Illinois was unable to immediately construct the said canal upon that plan whereby the waters of Lake [fol. 129] Michigan would flow through the said canal by gravity into the Desplaines river and thence into the Illinois.

That in the year 1848 the said Illinois and Michigan canal was finally completed upon the plan known as the shallow-cut plan, by which water of Lake Michigan necessary to partly operate the said canal and its locks were caused to flow into the canal by means of pumps then installed; that from the time the said canal was opened until the construction of the main channel of the Sanitary District, it furnished a partial outlet for the sewage and drainage of the City of Chicago; that as the needs of the City of Chicago demanded, said canal was enlarged so as to provide a better and more suitable outlet for the drainage of the City of Chicago and its environs; that on or about the year 1860, to meet the demands of increased population of the City of Chicago, larger pumps were installed to pump more water from Lake Michigan through the Chicago River into the Illinois and Michigan Canal, thence into the Desplaines River, thus causing part of the drainage and sewage of the City of Chicago and its environs to flow into the Desplaines River; that in the year 1865, to meet the further needs of the City of Chicago with reference to furnishing an outlet for its drainage and sewage, the General Assembly of the State of Illinois passed an act entitled, "An Act to provide for the completion of the Illinois and Michigan Canal upon the plan adopted by the State in 183 :." (Approved February 16, 1865; in force April 16, 1865): that the said act of the General Assembly of the State of Illinois is in words and figures as follows, to-wit:

An Act to Provide for the Completion of the Illinois and Michigan Canal upon the Plan Adopted by the State in 1836. (Approved February 16, 1865, in Force April 16, 1865.)

(Preamble.)—Whereas, it has been represented that the City of Chicago, in order to purify or cleanse Chicago River, by drawing sufficient quantity of water from Lake Michigan, directly through it, [fol. 130] and through the summit division of the Illinois and Michigan Canal, would advance a sufficient amount of funds to accomplish this desirable object; and,

Whereas, the original plan of the said canal was to cut down the summit so as to draw a supply of water for navigation directly from Lake Michigan, which plan was abandoned for the time being, after a large part of the work had been executed, only in consequence of the inability of the State to procure funds for its further prosecution; and,

Whereas, under the law creating the trust the plan of the summit division of the canal was changed, the level being raised so as to require the principal supply of water to be obtained through the Calumet feeder, subject to serious contingencies, and by pumping on to the summit with the hydraulic works at Bridgeport; now, therefore,

(Summit Division to Be Completed.)—Section 1. Be it enacted by the People of the State of Illinois, represented in the General Assembly: That to secure the completion of the summit division of the Illinois and Michigan Canal, upon the original "deep cut" plan, with such modifications and changes of line, if necessary, as will most effectually secure the thorough cleansing or purification of the Chicago River, and facilitate the execution of the work, the City of Chicago, through its constituted authorities, may at once enter into an arrangement with the board of trustees of said canal, with a view to the speedy accomplishment of the work.

(Opening and Closing of Canal.)—2. The canal shall not be constructed of a less capacity than the plan adopted by the canal commissioners in 1836, nor shall the work of deepening it be prosecuted so as to materially interfere with the navigation. By consent of the board of trustees, however, the navigation may be opened later and closed earlier than usual in former years, but it shall never be diminished to a less time than six months.

(Right of Way.)—3. It shall be lawful for the City of Chicago to enter upon and use any lands which may be necessary for the right of way for said canal, if the route should in any part vary from the present line of canal, and to take and use any materials of any description, necessary for the prosecution of the work contemplated, along the line thereof; the value of the same to be determined in the mode [fol. 131] provided by the general laws of this State.

(Amount Expended to be Lien—Proviso.)—4. The amount expended by the City of Chicago in deepening the summit division of the canal, according to the plan adopted by the canal commissioners in 1836, shall be a vested lien upon the Illinois and Michigan canal and its revenues, after the payment of the present canal debt; and the net revenues of the canal shall all, thereafter, be applied to the payment of the principal and interest of the same expended in accomplishing the object of this Act, until the whole amount is reimbursed to the city; Provided, the cost shall not exceed two and a half millions of dollars.

(State May Refund.)—5. The State of Illinois may at any time relieve this lien upon the canal and revenues, by refunding to the City of Chicago the amount expended in making the contemplated improvement and the interest thereon.

That under the said Act of 1865 the City of Chicago was authorized to improve the said Illinois and Michigan Canal by deepening same and otherwise changing its cross section so that a certain amount of the waters of Lake Michigan, including the sewage and drainage of the City of Chicago, would flow into and through the Illinois and Michigan Canal by gravity, and thence into the Desplaines River.

That on or about the year 1871 the said improvement was completed; that from that time to the time hereinafter stated, to wit, the year 1884, the waters of Lake Michigan, including the sewage and drainage of the City of Chicago and its environs flowed by gravity through the said Illinois and Michigan Canal into the Desplaines River; that from the time the said pumps were installed, to wit: the year 1848, water from Lake Michigan was caused to flow through the Chicago River in various quantities into the said Illinois and Michigan Canal and from thence into the Desplaines and Illinois Rivers; that when the said Illinois and Michigan Canal was completed upon the deep cut plan, a greater amount of water was caused to flow from [fol. 132] Lake Michigan into the said canal and from thence into the Desplaines and Illinois Rivers; that by the said works and the operation of the said pumps, the Chicago River was caused to flow in a reversed direction away from Lake Michigan instead of towards the lake, its current and course was reversed during the greater portion of each year; that thereby the needs of the City of Chicago and its environs for an outlet for its sewage and drainage were partially met.

That an ordinance of the City of Chicago passed on June 5th, 1865, providing for the improvement of the said Illinois and Michigan Canal is attached hereto as Exhibit "G" and made a part hereof.

That in the year 1871 the General Assembly of the State of Illinois, by an act entitled, "An Act to relieve the lien of the City of Chicago upon the Illinois and Michigan Canal and revenues by refunding to said city the amount expended by it in making the improvement contemplated by 'An Act to provide for the completion of the Illinois and Michigan Canal upon the plan adopted by the State in 1836,' approved February 16, 1865, together with interest thereon as authorized by Section 5 of said act, and to provide for issuing bonds therefor," provided for the payment to the City of Chicago of the moneys expended by it in improving the said Illinois and Michigan Canal upon the plan provided for in the Act of 1836.

That in the year 1881 the Senate and the House of Representatives of the State of Illinois passed a joint resolution, which said resolution is in words and figures as follows, to wit:

Resolution of 1881 (Laws 1881, p. 159)

Concerning Chicago Sewage in Illinois and Michigan Canal

Whereas, The State of Illinois, in General Assembly, did, on the [fol. 133] sixteenth day of February, 1865, grant and authorize the City of Chicago in the State of Illinois, to deepen the Illinois and Michigan canal for the purpose of, and with the intent to better the system of sewage of the said City of Chicago by permitting a free flow of water from Lake Michigan through the Chicago River and said canal to the Desplaines and Illinois Rivers; and the City of Chicago did perfect said improvement in conformity with said permission; and,

Whereas, The great fire in the said City of Chicago on the eighth and ninth days of October, A. D. 1871, did so greatly damage the assessable property of a very large number of its citizens and taxpayers, and the people of the State of Illinois did, by its General Assembly, refund to the said City of Chicago the amount of the cost of deepening the Illinois and Michigan Canal said sum refunded being in gross two millions nine hundred and fifty-five thousand three hundred and forty dollars; and,

Whereas, The deepening of the canal as aforesaid has proved to be totally inadequate for the purposes intended, and the large amount of sewage of the City of Chicago, being far greater than the capacity of the canal and the water now passing through it to deodorize and render innocuous; and,

Whereas, The foulness of the water annually causes the death of millions of fish in the Desplaines and Illinois Rivers, that float to the shores and decay; and,

Whereas, Said sewage, in an entirely undecomposed and putrid mass, is carried by the current of the canal into the Desplaines River, and thence into the Illinois River, and in its foulest condition is thus transported to and below the City of Peoria, in said State, rendering the air at all points along its passage so impure and foul as to be exceedingly offensive and taking with it germs of disease of all kinds prevalent in the City of Chicago, and thus spreading them broadcast through the entire Desplaines and Illinois River valleys, causing thereby much illness as well as poisoning of the blood, and debilitating the systems of 200,000 people; and,

Whereas, Careful investigation leads our people to fear that an epidemic may spread over said section of the State of Illinois from the causes above stated; and,

Whereas, in addition to the above distress, there has been a great [fol. 134] loss of property, business industries, and to the communities in said region, by reason of the causes herein mentioned; and,

Whereas, Prior to the deepening of said Illinois and Michigan Canal, the water necessary for all purposes of navigating said canal and propelling of machinery was obtained from the Desplaines River and the Calumet feeder, through Lane's Lake; and,

Whereas, The bed of the Desplaines River, at the summit and thence westward along the line of and adjacent to the canal, is, at a low state of water, eight (8) feet above the surface level of the canal, and will average a supply of water sufficient for all canal and power purposes during the seasons of navigation; and,

Whereas, The supplying of the canal from these sources will so dilute and weaken the sewage of the City of Chicago, as to greatly relieve it of its foulness and stench to the great delight, relief and health of the people near to and bordering upon the line of the canal, the Desplaines and Illinois Rivers; therefore, be it

Resolved, By the Senate, the House of Representatives concurring herein, That the Board of Canal Commissioners of the Illinois and Michigan Canal be, and they are hereby, directed to cause sluiceways of sufficient capacity, with the proper guard-gates, to be opened from the Desplaines River to the canal, at or near the summit, in Cook

County, and at or near Lemont, in Cook County, and also to construct a dam across the former Calumet feeder at such suitable point as will cause the waters from Lane's Lake to flow into the canal; that said canal commissioners shall immediately commence, construct and improve said sluices and feeders in the order named, and pay for the same out of any moneys in their hands or control as canal commissioners, resulting from the earnings of the canal. The amount to be expended as above designated in the prosecution of said improvement shall not, however, exceed the sum of ten thousand dollars: Provided, that the Canal Commissioners shall first confer with the Mayor or other proper authorities of the City of Chicago, and if said city shall proceed without delay to cause a flow into the canal from the Chicago River sufficient to dilute and purify the waters and thus remedy the evils complained of, said flow to be not less than 60,000 cubic feet per minute, including the ordinary flow [fol. 135] into the canal from the Chicago River, or so much thereof as in their judgment said canal can carry, and if this shall be accomplished by the first day of September, 1881, the commissioners shall accept it in lieu of obtaining a supply of water from the other sources named: Provided, further, that said commissioners are hereby directed to take care of 60,000 cubic feet per minute above contemplated, if so furnished by the City of Chicago: Provided, further, that the adoption of this resolution shall not commit the State to a system of permanent drainage of Chicago sewage through either the canal or Desplaines or Illinois Rivers, but that the State reserves the right to require the City of Chicago, in future years, to take care of its sewage through other channels: And provided, further, that if the said City of Chicago shall erect pumping works for the purpose of causing such flow as aforesaid, the Canal Commissioners shall allow the said city to erect said pumping works upon the canal lands in Bridgeport; and said city shall support, control and manage said pumping works, subject to the direction of the Canal Commissioners relative to the amount of water to be received into the canal, from time to time, as the exigencies of the canal may require, but at the expense of the said City of Chicago; Provided, further, that the City of Chicago, its officers, agents or employes, shall derive from this resolution no right to control or exercise any authority over any of the gates, locks or dams of said canal.

That under the said resolution the Board of Canal Commissioners of the Illinois and Michigan Canal were directed to permit the City of Chicago, if it so desired, to install pumps or such other works so that the flow of water through the said canal from Lake Michigan should be not less than 60,000 cubic feet of water per minute; that thereafter, on or about the year 1884, the City of Chicago did install pumps and works at Bridgeport so that waters of Lake Michigan including the sewage and drainage of the City of Chicago and its environs in greater quantities was caused to flow through the Chicago River and the Illinois and Michigan Canal and thence into the Illinois River to the extent of approximately 60,000 cubic feet of water per minute.

[fol 136] 25. This defendant states that the inhabitants of the City of Chicago and its environs obtained drinking water from Lake Michigan; that Lake Michigan was, is and will be the only adequate source from which drinking water for the metropolitan population of the City of Chicago and its environs could, or may be obtained; that Lake Michigan furnishes an adequate, sufficient, and pure supply of drinking water, if unpolluted by sewage or drainage; that the said additional flow of water through the Illinois and Michigan Canal created by the pumping works installed as aforesaid in 1884 at Bridgeport did not serve to sufficiently cleanse the Chicago River of the pollution created by the sewage and drainage of the City of Chicago and its environs; that during a portion of each year the Chicago River did flow into the Lake thus carrying with its waters the sewage and drainage of the City of Chicago and its environs, thereby further polluting the water of Lake Michigan from which the inhabitants of the City of Chicago and its environs obtained their drinking water supply; that the metropolitan district comprising the City of Chicago and other cities and villages located adjacent thereto and along the shores of Lake Michigan from the Indiana State line to the north line of the County of Cook had increased in population so that the improvements made from time to time up to the year 1884 were insufficient and inadequate to prevent the pollution of the water of Lake Michigan by sewage and drainage; that on account of this rapid increase of population a greater amount of sewage and drainage each year was discharged directly into the Lake and caused a greater pollution from the flow of the Chicago River at times towards Lake Michigan; that the inhabitants of the City of Chicago and its environs were thus deprived of a pure water supply for domestic purposes; that the water used for domestic purposes became so polluted by sewage and drainage injected into Lake Michigan that pestilence ensued, and it became necessary that some further [fol. 137] and better improvements be made by which the pollution of the drinking water of the inhabitants of the City of Chicago and its environs would be prevented; that Lake Michigan at and near the points where the City of Chicago and adjacent towns obtained their water supply had become so polluted and contaminated by sewage discharged into Lake Michigan from the Chicago River and from sewers emptying directly into said Lake Michigan, along its shores in the vicinity of the said water supply intakes that the death rate from typhoid fever and other water borne diseases had become very high; that deaths from such causes were frequent through the said City of Chicago and adjacent towns; that the Chicago River and its branches was then a seething mass of septic sludge giving forth noxious and disagreeable odors which caused annoyance and danger to the people of Chicago and persons visiting or sojourning within its limits.

That thereupon the City of Chicago, through its proper corporate authorities, appointed a commission consisting of eminent sanitary experts for the purpose of making an investigation of the conditions and making a report as to the proper solution of the problem then confronting the people of Chicago and its environs who depended

upon Lake Michigan for their water supply; that the said commission was appointed in the year 1886, and after several years of investigation and study, it presented a report to the Mayor of the City of Chicago recommending the construction of a channel and works connected therewith substantially as provided for in the said Act of May 29th, 1889; that the said Act of May 29th, 1889, under which the Sanitary District of Chicago, defendant, was organized, was passed pursuant to the investigations made by the said commission and other investigations made and carried on at the same time by other persons; that the said act was passed for the purpose of providing for the organization of a sanitary district and the construction of channels and works by it so that the pollution of the [fol. 138] drinking water of the City of Chicago and its environs would be relieved and a pure water supply could be secured; thereby preventing death and pestilence among the people of the City of Chicago and adjacent towns, arising from impure water and preventing active public nuisance created by the conditions then existing in the Chicago River as hereinbefore set forth.

26. This defendant further states that by the Act of May 29th, 1889, the Sanitary District organized under said act was authorized to construct a channel of sufficient size to take care of, not only the sewage and drainage of the City of Chicago and its environs, but it was authorized also to take care of the sewage and drainage of the City of Chicago and its environs as the increase of population might require; that in and by said act it was provided that said channel should be constructed with a capacity and size to produce and maintain through the rock sections thereof an ultimate flow of not less than 600,000 cubic feet of water per minute; that said channel was to be constructed so that it would produce and maintain at all times a continuous flow of not less than 20,000 cubic feet of water per minute for each 100,000 of the population within such sanitary district.

That the Chicago River drains an area of, to wit: 420 square miles; that the run-off of the said Chicago River drainage area at times of heavy rains and high flow is approximately 10,000 cubic feet of water per second; that in order to prevent the Chicago River from reversing itself in times of high flood and driving so much of said sewage into Lake Michigan, it was necessary that the channel so to be constructed should have an ultimate capacity of not less than 600,000 cubic feet of water per minute, or 10,000 cubic feet of water per second; that in order to prevent the pollution of the waters of Lake Michigan from and by way of the Calumet River, it was necessary that a channel be constructed connecting the said Calumet River with the main channel thus provided to be con- [fol. 139] structed so that the flow of the Calumet River would be reversed; that in order to prevent the pollution of the waters of Lake Michigan from the cities, villages and towns, located on the shores of Lake Michigan immediately north of the limits of the City of Chicago, it was necessary that a channel or adjunct be constructed

to provide an outlet into the main channel of the Sanitary District for the said cities, towns and villages.

That it was further provided in and by said act that the said main channel when completed should be a navigable water of the United States and that the said United States should have the authority to take over and operate said channel for navigation purposes, but not for sanitary or drainage purposes; that the said channel to be constructed pursuant to said act was intended to be an enlargement or a replacement of the channel known as the Illinois and Michigan Canal.

27. This defendant states that pursuant to said Act of May 29th, 1889, on to wit, the 15th day of August, 1889, a petition was duly filed, signed by the requisite number of legal voters, asking that the limits of the district be defined by the tribunal provided for in the act and praying that an election be held to determine whether the territory thus defined should become the Sanitary District of Chicago; that the tribunal so authorized did thereafter define the limits of this defendant; that the said election was held pursuant to the said petition and pursuant to the provisions of said act on the 5th day of November, 1889; that at the election so held on the 5th day of November, 1889, it was decided in the affirmative, that the territory so theretofore defined by the tribunal authorized as aforesaid become the Sanitary District of Chicago; that subsequently thereto and on or about the 12th day of December, 1889, a special election was held for the purpose of electing trustees of the Sanitary District of Chicago, and that as a result of said election, trustees [fol. 140] were duly elected; that subsequently thereto, on or about the 18th day of January, 1890, the Board of Trustees so elected at the election held on December 12, 1889, after duly qualifying as such trustees pursuant to the act, held a regularly organized meeting of the Board of Trustees to begin the actual work of constructing the Sanitary District channel provided for in said act. That this defendant entered upon the construction of the said main channel and other works provided for under said act long prior to September 19th, 1890; that pursuant to the said act of the General Assembly of the State of Illinois of May 29th, 1889, and long prior to September 19th, 1890, the Board of Trustees of the Sanitary District of Chicago laid out the plans for and entered upon the construction of the main channel from Robey Street in the City of Chicago to Lockport, Illinois, of a capacity of eight hundred and forty thousand cubic feet of water per minute, or 14,000 cubic feet per second; that plans were at the same time made and considered for the construction of a channel to connect the Calumet River with the said main channel; that plans were then made for the construction of intercepting sewers on the south side of the City of Chicago converging at 39th Street on the Lake Shore by which approximately 2,000 cubic feet of water per second should be pumped from Lake Michigan, together with sewage accumulated at said point, through a conduit to be constructed into the South Fork of the South Branch of the Chicago River, and from thence into the said main channel.

That the said intercepting sewers so provided for on the south side of the City of Chicago and converging at 39th Street were for the purpose of intercepting sewage that then flowed directly into Lake Michigan, and thereby divert it into the main channel.

That the North Branch of the Chicago River was then a stagnant stream into which sewage from a large portion of the north side of the City of Chicago was emptied; that in order to create a current [fol. 141] into said North Branch and thereby cleanse it and abate a public nuisance, plans were then made for the construction of a conduit extending from the Lake Shore at Lawrence Avenue in the City of Chicago to the said North Branch through which approximately 666 cubic feet of water per second from Lake Michigan should be caused to flow, and from thence into the main channel.

That plans were then made and considered for the construction of a north shore channel by which the sewage from the cities, towns and villages on the Lake Shore immediately north of the northern limits of the City of Chicago should be diverted from Lake Michigan into the North Branch of the Chicago River and from thence into the main channel; that it was contemplated that approximately 1,000 cubic feet of water per second from Lake Michigan should be caused to flow through the said channel, together with the sewage and drainage of said district.

That plans were then made and considered for enlarging the cross section of the Chicago River, South Branch, and West Fork to accommodate sufficient water so as to cause the course, current and flow of the Chicago River to be at all times reversed, in times of high water as well as in times of low water, and to provide for an ultimate flow through the Sanitary District main channel of sufficient water to dilute and purify the sewage of the City of Chicago and its environs flowing into the main channel, pursuant to the provisions of the said Act of 1889.

That at the time the defendant entered upon the construction of the said works the said complainant had knowledge of the said act and the improvements provided for under said act.

28. This defendant further states that pursuant to the said Act of 1889, and pursuant to the said plans it constructed a channel through what is known as the rock section of the route described, extending from the controlling works at Lockport north to Willow [fol. 142] Springs, a distance of 14.93 miles, with a bottom width of 160 feet, a surface width of 162 feet, with a depth of at least 24 feet, and with a declivity of to wit, 1 foot in every 20,000 feet, having a capacity of flowing 840,000 cubic feet of water per minute or 14,000 cubic feet of water per second; that from said Willow Springs to Robey Street, Chicago, Illinois, a distance of to wit, 13.1 miles, through what is known as the earth section, the defendant made plans for a channel with a bottom width of, to wit, 202 feet and a surface width of to wit, 300 feet and a depth of not less than, to wit, 24 feet, with a declivity of to wit, 1 foot in every 40,000 feet; that then said defendant constructed said channel through said earth section as planned, except in this, that for a distance of, to wit,

7.8 miles from Robey Street to Summit the defendant left unexcavated a width of 92 feet, inasmuch as said channel was out of the territory having a rock stratum and was more easily capable of progressive development as the population of the district might increase; that the capacity of said channel from Robey Street to Summit, being a portion of the earth section was, to wit, 80 per cent of the flow of the rock sections, or, to wit, 500,000 cubic feet of water per minute, or to wit, 8,000 cubic feet of water per second; that long prior to the filing of said Bill of Complaint herein, this defendant made and entered into a contract with the Great Lakes Dredge & Dock Company, under which the said main channel in the earth sections was to be enlarged by widening the same, so that through the said earth section, the said main channel would have a capacity of flowing in excess of 10,000 cubic feet of water per second; that before the filing of the said Bill of Complaint herein, the work provided for under said contract was substantially completed, so that the said main channel through the said earth sections at the time of the filing of said Bill of Complaint herein, had a capacity of flowing in excess of 10,000 cubic feet of water per second.

[fol. 143] 29. This defendant states that the aforesaid main channel from Robey Street to the controlling works at Lockport, Illinois, was completed and ready for use on or about September 21, 1898; that on or about January 11, 1899, the defendant, pursuant to the said Act of 1889, and more particularly Section 27 thereof, reported such fact to the Governor of the State of Illinois; that the Governor of the State of Illinois, pursuant to the said act, thereupon appointed a special commission to inspect and certify as to the completion of the main channel as required by the Act of 1889 aforesaid; that pursuant to the report of the said commission the then Governor of the State of Illinois did, on, to wit, January 17, 1900, authorize and direct the opening of said channel, the said commission having reported that the channel was completed in accordance with the provisions of said Act of 1889.

30. This defendant states that on, to wit, January 17th, 1900, the said channel was opened and the flow of the Chicago River, the South Branch and the West Fork thereof, as far as Robey Street, in the City of Chicago was reversed, and water was caused to flow out of Lake Michigan, through the Chicago River, the South Branch and the West Fork thereof, and down the Sanitary District channel from Robey Street and discharged into the Desplaines River at Lockport and from thence into the Illinois River, and from the Illinois River into the Mississippi River, and continuing to the Gulf of Mexico.

31. This defendant states that contemporaneously with the construction of the said main channel this defendant carried on certain construction work in the Chicago River, the South Branch thereof, and the West Fork to provide a larger cross section; that the purpose of enlarging the cross section was to enable the Chicago

River, the South Branch and the West Fork thereof to flow an increased quantity of water.

That on or about June 16, 1896, the defendant made application [fol. 144] to the Secretary of War for a permit to widen and deepen the Chicago River at certain points in accordance with a map or plan of such construction attached to the said application; that a copy of said application, together with a copy of said map or plan, is by express reference thereto, made a part hereof, and is attached hereto, marked "Exhibit H."

That on or about July 3, 1896, the Secretary of War granted a permit to the defendant to improve the Chicago River in accordance with the said application and the map accompanying the same, a copy of which said permit is, by express reference thereto made a part hereof and is attached hereto and marked Exhibit "I."

That on or about the 26th day of April, 1900, and on or about the 7th day of June, 1900, the said defendant made application to the Secretary of War for permits to make certain further changes, alterations and improvements in the South Branch of the Chicago River so as to accommodate a flow of water through the said South Branch and the West Fork thereof to the extent of the said applications, together with certain plans of the said improvement attached thereto, copies of which are by express reference thereto, made a part hereof and are attached hereto, marked Exhibit "J," and "JI," respectively, and said plans are marked K1 and K2, respectively.

That thereafter, and on or about July 11, 1900, the Secretary of War granted two permits to this defendant to make the changes, alterations and improvements in the South Branch of the Chicago River as shown upon the plans attached to said applications, that a copy of said permits are attached hereto and made a part hereof, and marked Exhibit "L" and "L1."

That pursuant to said permits of July 3, 1896, and July 11, 1900, and pursuant to certain other permits granted by the Secretary of War to this defendant at various times, to which other permits reference is hereby expressly made, this defendant improved the said [fol. 145] Chicago River, South Branch thereof and the West Fork, so that the said rivers have been enlarged sufficiently to accommodate a flow of water of at least 8,000 cubic feet per second with a velocity of not to exceed 1¼ miles per hour; that the volume of water above specified flowing as aforesaid through the said rivers and into and through the main channel of the Sanitary District, together with the 2,000 cubic feet of water per second emptying into the South Fork of the said Chicago River from the 39th Street Pumping Station will not create a current in any way injurious to navigation.

That in the course of the improvement of the said Chicago River and the widening and deepening thereof, and in the building of bridges, this defendant expended in excess of $10,000,000 as hereinbefore set forth: that a large part of the said money so expended was for the purpose of improving navigation in the said Chicago River, South Branch and West Fork: that the said Chicago River was deepened by this defendant to a depth of 26 feet from a depth

of 17 feet at all points and widened to a width of 200 feet at all points, from a width of approximately 100 feet.

That pursuant to the said Act of 1889 the said main channel or canal constructed by this defendant as aforesaid from Robey street to Lockport, Illinois, is of a depth of at least 24 feet at all points and of a width of at least 162 feet at all points; that the said Chicago River, the South Branch and the West Fork thereof as improved by this defendant, and the main channel constructed as aforesaid by this defendant, are of sufficient capacity to enable the largest vessels, freight or passenger, traversing the Great Lakes, to pass through or into same; that by virtue of the works of this defendant the largest vessels traversing the Great Lakes can pass through the said Chicago River and its branches as aforesaid to the City of Joliet; that the said main channel of this defendant as heretofore constructed is an enlargement, or takes the place of the old Illinois and Michigan Canal; [fol. 146] that since the completion of the said main channel the said Illinois and Michigan Canal has been abandoned; that the said improvement of the Chicago River and its branches, for the purpose of improving navigation was in accordance with the plans of the complainant in connection with the improvement of navigation upon the said rivers.

32. This defendant states that pursuant to an Act of the General Assembly of the State of Illinois entitled "An Act in relation to the Sanitary District of Chicago to enlarge the corporate limits of said district and to provide for the navigation of the channels created by said District, and to construct dams, water-wheels and other works necessary to develop and render valuable power arising from the water passing through its channels, and levying taxes therefor," approved May 14th, 1903, in force July 1, 1903, attached hereto as part of Exhibit "A," this defendant extended its main channel to the City of Joliet; that the said work was completed on or about the year 1907; that the portion of the said main channel constructed pursuant to said act was of the same depth and width as the portion of the main channel constructed pursuant to the Act of 1889; that under said act the said defendant constructed also certain works for utilization of water power at Joliet; that the water power so developed is approximately 30,000 horse power; that each horse power is worth approximately $30.00 per year net as developed at Joliet; that this defendant expended in the construction of the said water power development approximately $5,000,000; that if the flow of the said main channel of the Sanitary District were limited to 4,167 feet there would be little, if any, power developed or available at Joliet. That this defendant now sells and disposes of the electrical energy developed as aforesaid by its works at Joliet, Illinois; that such revenue is used for the purpose of partially defraying the other expenses of this defendant; that the hydro-electric plant constructed [fol. 147] as heretofore set forth near Joliet, Illinois, was constructed to utilize the water power incidentally developed by the flow through the main channel of this defendant for the purpose of diluting sew-

age arising from the population within the limits of the Sanitary District of Chicago; that the operation of the said hydro-electric plant and the development and sale of electrical energy does not in any way increase the amount of water caused to flow through the said main channel; that this defendant pursuant to the said Act of 1889 and the acts amendatory and supplementary thereto constructed the said North Shore Channel as an adjunct or addition to its main channel to furnish an outlet for the sewage and drainage of the District immediately north of the northern limits of the City of Chicago, comprising certain cities, towns and villages located along the shore of Lake Michigan and immediately north, as aforesaid, of the northern limits of the City of Chicago; that the said North Shore channel was completed on or about the year 1910; that there was also constructed at the point where the said North Shore channel intersects with Lake Michigan pumping works of sufficient capacity to cause approximately 1,000 cubic feet of water per second to flow into and through the said North Shore channel for the purpose of diluting the sewage and drainage of the said district.

34. This defendant states that pursuant to the said act of 1889 there was constructed by this defendant and the City of Chicago certain intercepting sewers and pumping works at Lawrence avenue, in Chicago, and the Lake, and at 39th Street, Chicago, and the Lake, by which all the sewage formerly flowing directly into Lake Michigan is diverted into the main channel aforesaid of this defendant.

That in the year 1910 this defendant entered upon the construction of an adjunct or addition to its main channel known or called the Calumet-Sag Channel extending from a point on the Little Calumet River at Blue Island to a point on the main channel of [fol. 148] this defendant at Sag, Illinois; that the said channel is now in the course of construction; that it is being constructed of a capacity to flow approximately 2,000 cubic feet of water per second, and is capable of enlargement, so that it will accommodate a flow of 4,000 cubic feet per second of water; that the said Calumet Sag Channel is designed to furnish an outlet for the sewage and drainage arising in what is called the Calumet district lying immediately south of the southern limits of the City of Chicago and thus prevent the pollution of the drinking water of the City of Chicago and environs by and through the Calumet River; that the said Calumet Sag Channel is also designed to furnish a certain amount of water by which to dilute sewage and drainage flowing through the main channel of the Sanitary District, and arising in that portion of the Sanitary District tributary to the Chicago River and its branches and the main channel of this defendant.

35. This defendant states that the said works constructed or being constructed and the said improvements made upon the Chicago River and its branches as hereinbefore described were made necessary by virtue of the said Act of the General Assembly of Illinois of 1889 and acts amendatory and supplementary thereto; that the

said works and improvements provide a complete and comprehensive system by which an outlet is provided for the sewage accumulating in the Metropolitan district comprised within the limits of the Sanitary District of Chicago, and for the drainage arising therein; that the said works so constructed and being constructed does and will prevent the pollution of the drinking water of the inhabitants of the Sanitary District and provide pure water for drinking and domestic purposes for the inhabitants of the District; that the said Act of 1889 and acts amendatory and supplementary thereto were passed and adopted by the General Assembly of the State of Illinois pursuant to and under the police power existing in the State for the purpose of protecting the health and lives of the people within [fol. 149] said district and within the State of Illinois as well as persons sojourning or visiting within the limits of this defendant.

That the channels and works constructed and to be constructed provides the only method by which the sewage and drainage of the inhabitants of the Sanitary District could be diverted from Lake Michigan and a pure water supply for domestic purposes secured for such inhabitants; that the drainage basin of the Great Lakes and that of the Mississippi River is divided by a ridge of ground within approximately 8 miles of the shore of Lake Michigan; that the summit of the said divide, known as the Continental Divide, was but a few feet above the level of Lake Michigan or Chicago City datum; that the City of Chicago and its environs is located in this regard differently from any other city on the Great Lakes; that by virtue of the nearness of the Mississippi River drainage basin and the insignificance of this so-called Divide it was possible to provide in the manner above set forth an outlet for the sewage and drainage of the City of Chicago and its environs so that the water of Lake Michigan could be maintained pure and undefiled by any pollution from sewage or drainage arising within the City of Chicago and other cities and villages located upon the shore of Lake Michigan near the said City of Chicago.

That this defendant and the City of Chicago have expended in and about the construction of the works and in making the improvements above mentioned the sum of to-wit, $82,000,000 to protect the said water supply; that of this amount the City of Chicago has expended approximately $6,500,000 in and about building intercepting sewers, pumping stations and other works.

36. This defendant further states that the said works constructed and the improvements made by this defendant hereinbefore set out and the works being constructed, were, and are necessary to preserve the health of the people within The Sanitary District of Chicago [fol. 150] and to protect the lives of the people therein; that the said The Sanitary District of Chicago comprises a large Metropolitan district within the County of Cook and various cities and villages located in said county; that this defendant attaches thereto a map or plat marked Exhibit "M," which is by express reference made a part hereof and attached hereto, which represents and shows the territorial boundaries of this defendant within which there is

comprised substantially three hundred eight-six square miles; that within the boundaries of said District there are situated the following cities, villages and towns: Chicago, Evanston, Glencoe, Winnetka, Wilmette, Shermerville, Glenview, Morton Grove, Niles, Cicero, Stickney, Evergreen Park, Morgan Park, Blue Island, Riverdale, Oak Park, Berwyn, Forest Park, River Forest, Maywood, Riverside, Brookfield, Bellwood, Franklin Park, Melrose Park, River Grove, Dolton, Harvey, West Hammond, Worth, Bremen and Calumet; that the population within the limits of the said The Sanitary District of Chicago exceeds two million five hundred thousand.

37. This defendant states that the Congress of the United States has at various times appropriated moneys for the improvements of the Illinois River and for the making of surveys and investigations to determine the best method by which the navigation upon the said Illinois and Desplaines rivers could be improved in connection with the Main Channel heretofore constructed by this defendant; that the said complainant built in the lower Illinois River certain dams at La Grange and Kampsville for the purpose of improving navigation upon the said Illinois River; that the said dams were built and constructed in connection with and for the purpose of supplementing the improvement of navigation made by the State of Illinois by the construction of two dams, one at Henry, Illinois, and the other opposite Copperas Creek on the Illinois River; that the said dams constructed by the complainant and by the State of Illinois were provided with locks by which vessels could pass from [fol. 151] the level of the water created by the dam at the lock to the level below, or vice versa; that during the period when the said main channel of this defendant was under construction, prior thereto and since the opening of same, the Congress has appropriated moneys for the purpose of making surveys and investigations for a Deep Waterway, extending from the terminus of the Main Channel of this defendant, at or near Lockport, Illinois, on the Desplaines and Illinois Rivers to the Mississippi River and from thence to the Gulf of Mexico; that all Boards of Engineers and all Engineer Officers of the Corps of Engineers of the United States Army, who have made reports in regard to such Deep Waterway pursuant to the appropriations made by the Congress have recommended the improvement of the Desplaines and Illinois Rivers to provide Deep Water navigation, and the plans and recommendations made by such engineers contemplate the use of the said Main Channel of this defendant as part of, and a link in such Deep Waterway and the use of the water flowing through and contemplated to be passed through the Main Channel of this defendant in the Desplaines and Illinois Rivers for the purpose of such navigation; that the International Waterways Commission created by an Act of Congress and by an Act of the Parliament of the Dominion of Canada by report made on January 11th, 1909, recommended that 10,000 cubic feet of water per second should be allowed to be diverted by this defendant from Lake Michigan; that this defendant constructed its said Main Channel, with a capacity of not less than Ten Thousand

(10,000) cubic feet of water per second, with the intended purpose to comply with the plans and purposes of the United States; that the United States approved of the said plans and purposes and the Congress of the United States co-operated with this defendant and invited this defendant to co-operate with complainant and joined with this defendant in the improvement of the Chicago River, as has [fol. 152] been more fully set out; that the Attorney General of the United States, on December 14, 1909, caused suit to be instituted in the name of the United States against the Economy Light & Power Company, in the Circuit Court of the United States, Eastern Division, Northern District of Illinois; that the said suit was instituted by way of a bill of complaint filed in said court to enjoin the said defendant, the Economy Light & Power Company, from constructing a dam in the Desplaines River; that in and by said bill of complaint, the said complainant further recognized the right of this defendant to divert the amount of water contemplated in and by its said work and in and by the said Act of May 29, 1889; that in and by said bill of complaint the said United States of America alleged:

"That in connection with the construction of said Sanitary District Canal, and in creating the system of waterways resulting from the construction of said canal, said State of Illinois has caused the quantity of water flowing through said Desplaines River below the point at which it connects with said canal to be largely increased, and that said portion of said river has been continuously since the opening of said canal, and is now, water navigable in fact and a part of the navigable waters of the United States and subject to the jurisdiction and control of the Federal Government. * * *

That in connection with and as a result of the construction of said Sanitary District Canal and the diversion of said water from Lake Michigan, said Sanitary District of Chicago, acting under authority of said State of Illinois, has largely increased the navigability of said Des Plaines River and that continuously since the opening of said canal there has been, and is, in said portion of said Des Plaines River below the point at which it connects with said canal, a body of water navigable in fact and which, by virtue of its connection with other navigable waters is to be deemed a part of the navigable waters of the United States and subject to the jurisdiction and control of said United States."

That the said complainant, in and by its said bill of complaint in the said cause wherein the Economy Light & Power Company is [fol. 153] defendant, based its right to an injunction enjoining the construction of the said dam upon the fact that the State of Illinois had, in and by and pursuant to the Act of May 29, 1889, created a navigable waterway in the Desplaines River at the points described in the said bill of complaint; that the said navigable water thus created and connected with and a part of the system of navigable waterways created by The Sanitary District of Chicago pursuant to the said Act of 1889 and which said waterways thus created were

connected with and a part of the other navigable waters of the United States; that, inasmuch as the said Act of 1889 provided for the recovery of damages of all and every kind sustained to land by virtue of the construction, operation and continuance of said main channel, that the Economy Light & Power Company had the right to obtain compensation for any damage that might have resulted to it by virtue of its being deprived of rights in the said Desplaines River at the points mentioned in the said bill of complaint which existed prior to the said Desplaines River becoming a navigable waterway pursuant to the said Act of 1889.

38. This defendant states that, at the time the said Act of 1889 was passed by the General Assembly of Illinois, and at the time the plans for construction of the said Main Channel were completed, and during the construction thereof, and before the opening of the said channel, the said United States had knowledge of and knew of the passage of the said Act, the making of the plans and the opening of the channel; that, at or about the time of the opening of the said channel, various measurements were made upon the St. Clair River to determine the increment thereof, by which the effect of a diversion of a certain number of feet of water from Lake Michigan outside of the regular outlet could be ascertained; that the measurements were made also, in the Niagara and St. Lawrence Rivers to determine the increment of such rivers respectively; that the said measurements [fol. 154] were made by the United States Lake Survey, under the direction of the Corps of Engineers of the United States Army; that, after the said measurements were made to determine the increments of the said rivers, it was claimed by various of the Engineer officers that the levels of Lake Michigan, Lake St. Clair, Lake Erie and Lake Ontario, and the channels connecting them, would be affected by the diversion of approximately ten thousand (10,000) cubic feet of water per second to the extent of approximately six (6) inches; that, thereafter, the United States, in providing for the improvement of the St. Mary's, St. Clair and Detroit Rivers and other channels connecting the Great Lakes with one another, determined upon a reference plane for such improvements at approximately six (6) inches below the reference plane that had theretofore been adopted, and the said United States did thereby acquiesce in and agree to such diversion.

And this defendant states that if the diversion of water from Lake Michigan has or will lower the levels of the water of either or all of the following named waters: Lake Michigan, Lake Huron, Lake St. Clair, Lake Erie, Lake Ontario, Sault Ste. Marie, St. Mary's River, St. Clair River, Detroit River, Niagara River, and St. Lawrence River and of all or any of the harbors, channels, canals or rivers connected therewith, it is feasible and practicable to compensate for the lowering of such levels by the building of proper works at either the St. Clair River, Detroit River, Niagara River, St. Lawrence River or of all of them; that the International Waterways Commission in their report on the regulation of Lake Erie issued in the year 1910, recommended the building of regulation works to regulate the levels of Lake Erie and thereby raise such levels approximately one foot at

low water times; that the said International Waterways Commission estimated the cost of building such regulation works at approximately seven hundred ninety-six thousand dollars; that the said International Waterways Commission has recently made a further report [fol. 155] upon the building of compensating or regulating works to regulate the levels of the various lakes in order to raise the level of Lake Erie approximately one foot; that the estimate made for said works by the said Commission as the cost of said work is approximately three million dollars; that such regulation works would more than offset any alleged lowering of the levels of Lake Michigan, Lake Huron and Lake Erie by the diversion of water through the Chicago Drainage Canal as contemplated under the said Act of 1889 and as proposed by the works of this defendant already constructed and in the process of construction; that the levels of the water of Lake Michigan, Lake Huron, Lake St. Clair, Lake Erie, Lake Ontario, Sault Ste. Marie, St. Mary's River, St. Clair River, Detroit River, Niagara River, St. Lawrence River and all the harbors, channels, canals and rivers connected therewith, have been lowered by the works constructed by the United States, by Canada, by private individuals and corporations, by and with the consent and acquiescence of the said United States; that the level of said waters has not been lowered by this defendant.

39. This defendant states that the said complainant, by consenting to the improvement of the Chicago River to accommodate the flow of water through the Main Channel of this defendant as contemplated under the Act of 1889, by the appropriation of money for the purpose of determining the feasibilty of improving waterways to connect with the navigable waterways created by this defendant, by acquiescing in and acknowledging the right to use the said works and to abstract the water from Lake Michigan contemplated by said Act of 1889, solemnly asserted in the said case of the United States vs. The Economy Light & Power Company, above referred to, by allowing this defendant to proceed with the construction of said works with the knowledge of the said complainant, without making any objection thereto, but on the contrary, consenting to and agreeing to [fol. 156] various improvements made necessary by virtue of the said system of works provided for under said Act of 1889, has estopped itself from making any objection to or attempting to prevent further use and continuance of the said works for the purpose for which they were created; that, after the initiation of the said work of the said Sanitary District upon its said system of drainage, the said United States adopted the improvements contemplated and being then carried on by the Sanitary District in the Chicago River and its various branches and supplementing said improvements so being made by this defendant, and inviting further improvements, itself expended approximately one million dollars ($1,000,000.00) in the improvement of the Chicago River from Rush street to the head of the West Fork.

40. This defendant states that this defendant has never recognized the right of the United States in any manner to interfere with the

construction, operation or use of the Main Channel of the Sanitary District or any of its adjuncts or additions; that it has never recognized the right of the United States in any manner to determine or direct how the said Main Channel or its adjuncts or additions, as hereinbefore mentioned, should be operated or used, or the amount of water that should be abstracted from Lake Michigan through its various channels or adjuncts or additions thereto to carry out the provisions of said Act of May 29, 1889; that this defendant made application for the permits mentioned and described in the Bill of Complaint, copies of which are attached to the Bill of Complaints as exhibits, by reason of the close blending or association of the two governments, namely, the Governments of the State of Illinois and the United States of America; that this defendant desired, if possible, to obtain the consent of the Secretary of War to the construction, operation and use of its works but this defendant never has admitted and does not admit, but on the contrary denies the right of the United States to determine the amount of water that should be [fol. 157] caused to flow through the said Main Channel or its additions or adjuncts, or the manner of such flow; that the permit of May 8, 1899, granted to this defendant the right to open the said Main Channel and use the same for the purposes and to cause the amounts of water to flow therein as contemplated and provided for under the Act of May 29, 1889; that the only condition mentioned in the said permit limiting the amount of water which the Secretary of War consented should be allowed to flow through the said Main Channel, was the preservation of suitable conditions of navigation upon the Chicago River itself; that the said condition was inserted in the said permit and made necessary by virtue of the fact that, at that time, the said Chicago River had not been widened and deepened to the extent that it was proposed to be; that the orders subsequently given by the Secretary of War to reduce the flow or to increase the flow of water through the Chicago River were based entirely upon the conditions of the Chicago River for the purpose of navigation; that in and by the said permit of May 8, 1899, and the subsequent orders and permits issued by the Secretary of War, the said United States recognized the right of this defendant to abstract water from Lake Michigan and only limited the amount of such abstraction by the amount that the Chicago River could carry without injury to navigation thereon; that, subsequently to the issuance of the said permits, the said project of this defendant, for the widening and deepening of the said Chicago River, for a capacity of at least eight thousand (8,000) cubic feet of water per second, was carried out pursuant to the consent of the Secretary of War, as evidenced by the permits hereinbefore mentioned; that, before the filing of the bill of complaint herein, this defendant improved the said Chicago River by widening and deepening the same, so that at least eight thousand (8,000) cubic feet of water per second could flow and was flowing into and through the said Chicago River, the South [fol. 158] Branch and West Fork thereof, without creating a current of more than one and one-quarter (1¼) miles per hour and without creating a condition which would be or was injurious to navigation,

but on the contrary, the condition so created by this defendant greatly improved the navigation in all respects of said Chicago River and all its branches.

41. This defendant states that the said water discharged from the said main channel into the Desplaines River, flows through said Desplaines River and empties into the Illinois River; that, as a result of the discharge of water into the said Illinois River, the said Illinois River has become navigable without the use of the Government dams or the State dams heretofore constructed, so that the Illinois River may be traversed by boats of a deeper draft than could have traversed the said Illinois River by the use of the locks and dams constructed by the United States Government and the State of Illinois, namely, the Kampsville and La Grange dams by the United States and the Henry and Copperas Creek dams by the State of Illinois; that the Illinois River has become clear, which prior to the opening of the said main channel was a sluggish, slow moving body of water, badly polluted by sewage discharged by the City of Chicago and many towns and villages situated along said Illinois River; that by reason of the said increased flow of water in said river, fish life in said river has increased very rapidly, and the said Illinois River has become more healthful to the people living thereon; that the cities and towns located on the said Illinois and Desplaines Rivers are enabled, by virtue of the said flow of water, created by this defendant, to discharge their sewage into the said river without creating an offensive condition or public nuisance; that, if the said flow of the said Illinois River had not been increased by the waters caused to flow therein by this defendant, or, if the flow through the main channel of this defendant were limited to four thousand one [fol. 159] hundred and sixty-seven (4,167) cubic feet of water per second, or to any amount materially less than required by said Act of May 29, 1889, it would be necessary for the cities and towns located on the said Illinois and Desplaines Rivers to expend vast sums of money in treating the sewage now discharged into the said Illinois River, in order to prevent an offensive condition or public nuisance.

42. This defendant states that, since the opening of the said main channel and the completion and opening of additions and adjuncts thereto, including the intercepting sewers hereinbefore described, the health conditions in the City of Chicago and other towns and villages located within the limits of The Sanitary District of Chicago have greatly improved; that the death rate from water borne diseases has greatly diminished; that in and by the said works created by this defendant pursuant to the said Act of 1889 and acts amendatory and supplementary thereto, persons living or sojourning within the district have acquired a pure water supply for drinking and other domestic purposes; that the City of Chicago is a great railroad and commercial center, and is a primal market; that a great many persons who do not reside within the limits of the Sanitary District come each year from all parts of the United States and the world to the City of Chicago and remain therein for various periods; that the total number of persons coming into and leaving the City of Chi-

cago each year approximates twenty-seven million (27,000,000) people; that there are, in addition, approximately forty-seven million (47,000,000) persons who do not reside within the City of Chicago who come to the City from nearby or suburban towns and villages during the course of each year; that all such persons traveling through said City of Chicago or sojourning therein for any length of time, are interested in the better health conditions produced by a pure and unpolluted or undefiled drinking water supply.

[fol. 160] 43. This defendant states that, if the injunction prayed for by the complainant herein is granted, and this defendant is obliged thereby to limit its flow of water to four thousand, one hundred sixty-seven (4,167) cubic feet per second, a large portion of the moneys already expended by this defendant and the City of Chicago in and about the construction and installation of the works hereinbefore mentioned and described, will have been used for no purpose and the said works will become practically useless and of no substantial efficiency or value; that the said City of Chicago and other cities, towns and villages within the boundaries of this defendant have constructed their sewers, water mains, and other sewage disposal works and water supply works upon the basis that the works of this defendant were and are permanent, to endure for all time, and could be used and operated as contemplated by the said Act of May 29, 1889, and acts amendatory and supplementary thereto; that, if the said flow of water through the said main channel of this defendant and its adjuncts and additions should be limited to four thousand one hundred sixty-seven (4,167) cubic feet of water per second, it will be necessary, in order to prevent said sewage from becoming a public nuisance, to construct a plant or plants for the disposal of sewage by some other method or methods; that the construction of such plant or plants would cost upwards of one hundred millions of dollars ($100,000,000) and the annual operation of such a system would cost over seven million dollars ($7,000,000) which capitalized at five per cent (5%) would mean a total investment of two hundred and forty million dollars ($240,000,000); that it would be necessary, also, to construct, in connection with the said sewage disposal works, filtration works to filter all the drinking water and water used for domestic purposes of the inhabitants of said District and the floating population thereof, which would cost upwards of twenty-five millions of dollars ($25,000,000) and which would [fol. 161] require an annual operation charge of at least two million dollars ($2,000,000), which, capitalized at five per cent (5%) would be equal to an original investment of forty million dollars ($40,000,000); that the City of Chicago and the other cities, towns and villages located within the boundaries of the Sanitary District, would be thus damaged to the extent of approximately three hundred million dollars ($300,000,000) and the works of this defendant already completed and in operation would become useless and the moneys expended by this defendant in the construction thereof, approximately eighty-two million dollars ($82,000,000), would be expended for no practical purpose so far as taking care of the sanitary condi-

tions of this defendant are concerned; that the only method by which this defendant can efficiently take care of and remove the sewage and drainage arising within its limits and thereby protect the water supply of the inhabitants of the City of Chicago and its environs is the one laid out under the said Act of May 29, 1889, and acts amendatory and supplementary thereto; that the method or methods which it would be necessary for this defendant to adopt, if the flow of water through its main channel were limited to four thousand, one hundred sixty-seven (4,167) cubic feet per second would not accomplish the purpose now secured by the works of this defendant constructed as hereinbefore set forth, nor would such works constructed under a plan made necessary by such limitation of flow of water in any manner equal the efficiency of the works already constructed to be operated pursuant to the provisions of the said Act of 1889.

44. This defendant states that the State of Illinois under the said Act of 1889 and acts amendatory and supplementary thereto, provided a comprehensive and effective method to dispose of the sewage of the metropolitan district comprised within the boundaries of this defendant, and to provide pure drinking water [fol. 162] for the inhabitants thereof and its floating population, to wit: the method of treating the said sewage by dilution and diverting the same from Lake Michigan; that this defendant is without power to dispose of sewage and to provide a pure drinking water supply by any other method than the one provided for under the said Act of 1889 and acts amendatory and supplementary thereto; that, if it were given power to dispose of the sewage by some other method and to procure a pure drinking water supply in some other manner, the constitutional limitation of the State of Illinois upon the creation of indebtedness by municipalities would prevent this defendant from providing the moneys with which to build sewage disposal works and filtering plants to meet the conditions which would be created by the decrease of the flow of water to four thousand, one hundred sixty-seven (4,167) cubic feet per second, and it would be impossible for this defendant, if it had the power, to provide sufficient funds to build such sewage disposal and filtration works, either by taxation or by the issuance of bonds; that neither the City of Chicago nor the other cities, villages or towns within the limits of The Sanitary District of Chicago, have the power to raise sufficient moneys by the sale of bonds or by taxation, by reason of the constitutional limitation aforesaid, to build sewage disposal or water purification and filtration works which would be necessary to be constructed within the limits of the respective cities, towns and villages, if this defendant were compelled to limit the flow of water to four thousand, one hundred and sixty-seven (4,167) cubic feet per second.

45. This defendant states that, if the said injunction is granted, and this defendant is restrained from withdrawing more than four thousand, one hundred sixty-seven (4,167) cubic feet per second from Lake Michigan, it will be unable to keep the drainage water,

which will flow from said territory, from reversing the Chicago [fol. 163] River at various times during each year, so that the said drainage and sewage arising tributary to the Chicago River will flow into Lake Michigan and thereby pollute the water supply of the City of Chicago and other cities, towns and villages within the limits of the Sanitary District; that, at other times of the year, the said Chicago River will become polluted so that there would be thereby created an offensive condition and a public nuisance, increasing the spread of water-borne diseases, endangering the health and lives of the entire population of this defendant and its floating population.

46. This defendant states that the sewage disposal works and water filtration plants that would be made necessary to be constructed if the said injunction were granted and the flow of water through the main channel were limited to four thousand, one hundred and sixty-seven (4,167) cubic feet per second, would be inadequate, ineffective and impracticable to provide for the disposition of the sewage aforesaid and to provide pure drinking water for the inhabitants of the said District; that purification of sewage artifically and the filtration of water polluted by sewage or an effluent arising from sewage purification work is a method for providing a water supply used only where the method provided for under the Act of 1889, to wit: the dilution method and diverting sewage and drainage from the water supply, is impossible.

47. This defendant denies that the complainant is entitled to the relief, or any part thereof, as in the said Bill of Complaint demanded, and this defendant states that said Bill of Complaint is inadequate, and insufficient in law and does not on its face entitle the said complainant to the relief prayed for in and by said Bill of Complaint; and this defendant furthermore moves that the Bill of Complaint be dismissed for want of equity and this defendant, as to [fol. 164] each and every allegation of the said Bill of Complaint not herein admitted, answered or specifically denied hereby expressly denies, and this defendant prays the same advantage of this answer as if it had pleaded or demurred to the said Bill of Complaint and prays that it be dismissed with its reasonable costs and charges, in this behalf most wrongfully sustained.

Edmund D. Adcock, Alfred S. Austrian, Solicitors for Defendant.

[fol. 165] EXHIBIT A TO ANSWER

An Act to Create Sanitary Districts and to Remove Obstructions in the Desplaines and Illinois Rivers. (Approved May 29th, 1889. In force July 1, 1889, L. 1889, P. 126; Legal News Ed. p. 85.)

343. Incorporating Sanitary District—Question, How Submitted—Commissioners—Report as to Expenditures.

1. That whenever any area of contiguous territory within the limits of a single county shall contain two or more incorporated

cities, towns or villages, and shall be so situated that the maintenance of a common outlet for the drainage thereof will conduce to the preservation of the public health, the same may be incorporated as a sanitary district under this act, in the manner following: Any 5,000 legal voters resident within the limits of such proposed sanitary district may petition the county judge of the county in which they reside to cause the question to be submitted to the legal voters of such proposed district whether they will organize as a sanitary district under this act. Such petition shall be addressed to the county judge, and shall contain a definite description of the territory intended to be embraced in such district, and the name of such proposed sanitary district: Provided, however, that no territory shall be included in any municipal corporation formed hereunder which is not situated within the limits of a city, incorporated town or village, or within three miles thereof, and no territory shall be included within more than one sanitary district under this Act. Upon the filing of such petition in the office of the county clerk of the county in which such territory is situated it shall be the duty of the county judge to call to his assistance two judges of the circuit court and such judges shall constitute a board of commissioners who shall have [fol. 166] power and authority to consider the boundaries of any such proposed sanitary district, whether the same shall be described in such petition or otherwise. Notice shall be given by such county judge of the time and place where such commissioners will meet, by a publication inserted in one or more daily papers published in such county, at least twenty days prior to such meeting. At such meeting the county judge shall preside and all persons in such proposed sanitary district shall have an opportunity to be heard touching the location and boundary of such proposed district and make suggestions regarding the same, and such commissioners, after hearing statements, evidence and suggestions, shall fix and determine the limits and boundaries of such proposed district, and for that purpose and to that extent, may alter and amend such petition. After such determination by said commissioners, or a majority of them, the county judge shall submit to the legal voters of the proposed sanitary district the question of the organization and establishment of the proposed sanitary district, as determined by said commissioners, at an election to be held on the first Tuesday after the first Monday in November thence next ensuing, notice whereof shall be given by said commissioners, at least twenty days prior thereto, by publication in one or more daily papers published within such proposed sanitary district, such notice to specify briefly the purpose of such election, with a description of such proposed district. Each legal voter resident within such proposed sanitary district shall have the right to cast a ballot at such election, with the words thereon "For Sanitary District," or "Against Sanitary District." The ballots so cast shall be received, returned and canvassed in the same manner and by the same officers as is provided by law in the case of ballots cast for county officers. The County judge shall cause a statement of the result of such election to be spread upon the records of the County Court. If a majority of the votes

cast upon the question of the incorporation of the proposed sanitary [fol. 167] district shall be in favor of the proposed sanitary district such proposed district shall thenceforth be deemed an organized sanitary district under this act:* Provided, that the Trustees of all Sanitary Districts heretofore created under this act and all Sanitary Districts hereafter to be created under this act, whenever the expenditures of any such District shall have amounted to the sum of one million dollars and such sum shall have been raised; by taxation upon the assessable property in any such Sanitary District or shall have been raised by the sale of bonds of said district or otherwise, shall on or before September 1, A. D. 1905, report to the Governor of this State and to the two branches of the Legislature thereof separately all of the items of expenditures theretofore made by them as such Trustees, of the moneys so belonging to said Sanitary District, together with all items of receipts from all sources and shall furnish with all such reports copies of all contracts entered into by them for the expenditure of moneys so belonging to said District and upon November 30, A. D. 1906, and biennally thereafter the Trustees of any such District shall make full, complete, accurate and itemized reports of all receipts and expenditures of such moneys to be hereafter made by them respectively, together with a copy of all contracts for the expenditures of moneys hereafter to be made by such Trustees to the Governor and the two branches of the State Legislature of this State separately and the Governor and either branch of the said Legislature of this State shall have the right to examine the books of said Trustees and all Expenditures made by or in any such District, by committee or otherwise, and to call for further reports, accounts, items and copies of all contracts made by or documents held in the possession of any such Trustees; and upon the failure, refusal or neglect of any such Trustees to accurately and completely furnish any and all such items, accounts, documents and reports of contracts as provided in this Act, any and all Trustees of any such [fol. 168] Sanitary District shall forfeit their office and by writ of quo warranto be ousted and removed therefrom; all such actions to be brought in the county where any such Trustees may reside or wherein the major portion of any such Sanitary District may be situated. (That part following the star was added by the Act of 1905 entitled "An Act to amend and revise section 1 of an act entitled, 'An Act to create Sanitary Districts and to remove obstructions in the Desplaines and Illinois Rivers.'" (Approved May 29th, 1889, in force July 1, 1889. Approved May 13, 1905. In force July 1, 1905.)

344. Judicial Notice of District — Organization — Election — County Judge.

2. All courts in this state shall take judicial notice of the existence of all Sanitary Districts organized under this act. Upon the organization of any sanitary district under this act the county judge shall call an election to elect officers and cause notice thereof to be posted or published, and perform all other acts in reference to such election in like manner as nearly as may be, as he is required to perform in

reference to the election of officers in newly organized cities under the provisions of an act entitled "An Act to provide for the incorporation of cities and villages." Approved April 10th, 1872.

345. Trustees—Election and Terms of—Vacancy.

3. In each Sanitary District organized under this act, there shall be elected at the November election 1905, nine trustees, three of which trustees shall hold their office for a term of one year, three for a term of three years, and three for a term of five years, and until their successors shall be elected and qualified.

At every regular county election occurring after the year 1905, there shall be elected three trustees who shall hold their office for six [fol. 169] years, and until their successors shall be elected and qualified, to succeed those whose terms of office shall expire that year. In all elections for trustees each elector may vote for as many candidates as there are trustees to be elected, but no elector may give to such candidates more than one vote, it being the intent and purpose of this act to prohibit cumulative voting in the selection of members of the Board of Trustees of the Sanitary District.

Each elector in such Sanitary District may vote for and designate (upon his ballot cast for Trustees for said Sanitary District) one of the candidates for Trustees to be President of said Board, and the person so designated who shall receive the highest number of such votes shall be declared elected President of such board. The person so elected, President of such Board at the November election of 1905, shall hold office for a term of five years and until his successor shall be elected and qualified. When a vacancy shall occur in the office of president of such board, the board of trustees shall elect one of their number, who shall perform the duties of president until such vacancy shall be filled by an election. When a vacancy shall occur in the office of trustees of any sanitary district organized under the provisions hereof within one year before the expiration of the term of such vacant office, the vacancy shall be filled by appointment by the board of trustees of such sanitary district, but if such unexpired term exceeds one year, the Governor shall appoint the time for an election to fill such vacancy, and shall file a notice of such time with the county clerk of each of the counties in which (such) sanitary district shall be situated.

Such sanitary district shall from the time of the first election held by it under this act be construed in law and equity a body corporate and politic, and by the name and style of the Sanitary District of —— and by such name and style may sue and be sued, contract and be contracted with, acquire and hold real estate and personal property necessary for corporate purposes, and adopt a com- [fol. 170] mon seal and alter the same at pleasure. (As amended by act approved and in force February 27, 1907. L. 1907, p. 287.

346. Trustees Constitute a Board—Duties and Powers of—Ordinances, etc. (How Approved).

4. The trustees elected in pursuance of the foregoing provisions of this act shall constitute a board of trustees for the district by which

they are elected, which board of trustees is hereby declared to be the corporate authorities of such sanitary district, and shall exercise all the powers and manage and control all the affairs and property of such district. Said board of trustees shall have the right to elect a clerk, treasurer, chief engineer and attorney for such municipality, who shall hold their respective offices during the pleasure of the board, who shall give bond as may be required by said board. Said board may prescribe the duties and fix the compensation of all the officers and employees of said sanitary district: Provided, however, that the salary of the president of said board of trustees who shall be elected at any election held subsequent to the year 1910 shall in no case exceed seven thousand five hundred dollars ($7,500.00) per annum and the salary of each of the other trustees elected subequent to the year 1910, shall not exceed five thousand dollars ($5,000.00) per annum. Any incumbent of the office of trustee (excepting said president) whose term is now running and does not expire until after the passage of this act may appoint a private secretary, and such appointment shall remain in force until revoked by the trustee making the same, and such secretary shall receive a salary at the rate of two thousand dollars ($2,000.00) per annum, payable monthly. No trustee (excepting the president) shall be entitled to appoint such private secretary during such time as he shall receive the maximum salary herein authorized. Any incumbent of the office of president heretofore or hereafter elected may appoint a private secretary, which secretary shall receive a salary [fol. 171] not to exceed three thousand five hundred ($3,500.00) dollars per annum, payable monthly. Any such appointment made by the president shall remain in force until revoked by such president or until the expiration of his term of office.

Said board of trustees shall have full power to pass all necessary ordinances, orders, rules, resolutions and regulations for the proper management and conduct of the business of said board of trustees and of said corporation and for carrying into effect the object for which such sanitary district is formed. All ordinances, orders, rules, resolutions and regulations passed by said board of trustees shall, before they take effect, be approved by the president of said board of trustees, and if he shall approve thereof, he shall sign the same, and such as he shall not approve he shall return to the board of trustees with his objections thereto in writing at the next regular meeting of said board of trustees occurring after the passage thereof. Such veto may extent (extend) to any one or more items or appropriations contained in any ordinance making an appropriation, or to the entire ordinance; and in case the veto extends to a part of such ordinance, the residue thereof shall take effect and be in force, but in case the president of such board of trustees shall fail to return any ordinance, order, rule, resolution or regulation with his objections thereto by the time aforesaid, he shall be deemed to have approved the same, and the same shall take effect accordingly. Upon the return of any ordinance, order, rule, resolution or regulation by the president, the vote by which the same was passed shall

be reconsidered by the board of trustees, and if upon such reconsideration two-thirds of all the members elect shall agree by yeas and nays to pass the same it shall go into effect notwithstanding the president may refuse to approve thereof. (As amended by act approved May 27, 1911. In force July 1, 1911. L. 1911, p. 307.)

[fol. 172] 347. Ordinances Making Appropriaton—Publication of.

5. All ordinances making any appropriations shall, within one month after they are passed, be published at least once in a newspaper published in such district, or if no such newspaper of general circulation is published therein, by posting copies of the same in three public places in the district; and no such ordinance shall take effect until ten days after it is so published, and all other ordinances, orders and resolutions, shall take effect from and after their passage unless otherwise provided therein.

348. Ordinances and Resolutions—Evidence.

6. All ordinances, orders and resolutions, and the date of publication thereof, may be proven by the certificate of the clerk, under the seal of the corporation, and when printed in book or pamphlet form, and purporting to be published by the board of trustees and such book or pamphlet shall be received as evidence of the passage and legal publication of such ordinances, orders and resolution, as of the dates mentioned in such book, or pamphlet in all courts and places without further proof.

349. Board of Trustees—Powers of.

7. The board of trustees of any sanitary district organized under this act shall have power to provide for the drainage of such district by laying out, establishing, constructing and maintaining one or more main channels, drains, ditches, and outlets for carrying off and disposing of the drainage (including the sewage) of such district, together with such adjuncts and additions thereto as may be necessary or proper to cause such channels or outlets to accomplish the end for which they are designed in a satisfactory manner; also to make and establish docks adjacent to any navigable channel made under the provisions hereof for drainage purposes, and to lease, [fol. 173] manage and control such docks, and also to control and dispose of any water power which may be incidentally created in the construction and use of said channels or outlets, but in no case shall said board have any power to control water after it passes beyond its channel, waterways, races or structures into a river or natural waterway or channel, or water-power or docks situated on such river or natural waterway or channel: Provided, however, nothing in this act shall be construed to abridge or prevent the State from hereafter requiring a portion of the funds derived from such water-power, dockage or wharfage to be paid into the State Treasury to be used for State purposes. Such channels or outlets may extend outside of the territory included within such sanitary dis-

trict and the rights and powers of said board of trustees over the portion of such channel or outlet lying outside of such district shall be the same as those vested in said board over that portion of such channels or outlets within the said district.

350. May Purchase and Sell Real Estate, etc.

8. Such sanitary district may acquire by purchase, condemnation or otherwise any and all real and personal property, right of way and privilege, either within or without its corporate limits, that may be required for its corporate purposes: Provided, all moneys for the purchase and condemnation of any property shall be paid before possession is taken, or any work done on the premises damaged by the construction of such channel or outlet, and in case of an appeal from the court in which such condemnation proceedings shall be pending, taken by either party, whereby the amount of damages is not finally determined, the amount of the judgment in such court shall be deposited with the county treasurer of the county in which such judgment shall be rendered subject to the payment of such damages on orders signed by such judge whenever the amount of damages is finally determined; and when not longer required for such purposes, [fol. 174] to sell, convey, vacate, and release the same, subject to the reservation contained in section 7 relating to water-power and docks. (As amended by act approved May 25, 1907. In force, July 1, 1907; L. 1907; p. 284.)

351. May Borrow Money—Limitation.

9. The corporation may borrow money for corporate purposes, and may issue bonds therefor, but shall not become indebted in any manner, or for any purpose to an amount in the aggregate to exceed three (3) per centum of the valuation of taxable property therein, to be ascertained by the last assessment for State and county taxes previous to incurring of such indebtedness. (As amended by act approved June 14, 1909. In force July 1, 1909. L. 1909, P. 196.)

352. To Provide for Direct Annual Tax—Net Earnings.

10. At the time or before incurring any indebtedness, the board of trustees shall provide for the collection of a direct annual tax sufficient to pay the interest on such debt as it falls due, and also to pay and discharge the principal thereof as the same shall fall due, and at least within twenty years from the time of contracting the same: Provided, that the net earnings from water-power and docks may be appropriated and applied to the purpose of paying the interest or principal of such indebtedness, or both, and to the extent that they will suffice, the direct tax may be remitted.

353. Contracts—How Let.

11. All contracts for work to be done by such municipality, the expense of which will exceed five hundred dollars, shall be let to the lowest responsible bidder therefor upon not less that ten days' public notice of the terms and conditions upon which the contract is to be

let having been given by publication in a newspaper of general circulation published in said district, and the said board shall have the [fol. 175] power and authority to reject any and all bids and readvertise: Provided, no person shall be employed on said work unless he be a citizen of the United States, or has in good faith declared his intention to become such citizen. In all cases where an alien, after filing his declaration of intention to become a citizen of the United States, shall for the space of three months after he could lawfully do so, fail to take out his final papers and complete his citizenship, such failure shall be prima facie evidence that his declaration of intentions was not made in good faith. And that eight hours shall constitute a day's work. (As amended by act approved May 25, 1907. In force July 1, 1907. L. 1907, p. 284.)

354. Trustees—Levy and Collect Taxes—Movable Bridges.

12. The board of trustees may levy and collect taxes for corporate purposes upon property within the territorial limits of such sanitary district, the aggregate amount of which in any one year shall not exceed one per centum of the value of the taxable property within the corporate limits as the same shall be assessed and equalized for the county taxes for the year in which the levy is made. Said board shall cause the amount to be raised by taxation in each year, to be certified to the county clerk on or before the second Tuesday in August as provided in section one hundred and twenty-two of the general revenue law. All taxes so levied and certified shall be collected and enforced in the same manner and by the same officers as state and county taxes, and shall be paid over by the officer collecting the same to the treasurer of the sanitary district, in the manner and at the time provided by the general revenue law: Provided, that no part of the taxes hereby authorized shall be used by such drainage district for the construction of permanent fixed, immovable bridges across any channel constructed under the provisions of this act; And provided further, that all bridges built across such channel shall not necessarily interfere with or obstruct the navigation of such channel. [fol. 176] when the same becomes a navigable stream, as provided in section 24 of this act, but such bridges shall be so constructed that they can be raised, swung, or moved out of the way of vessels, tugs, boats, or other water craft navigating such channel; And provided further that nothing in this act shall be so construed as to compel said district to maintain or operate said bridges, as movable bridges, for a period of nine years from and after the time when the water has been turned into said channel pursuant to law, unless the needs of general navigation on the Des Plaines and Illinois rivers, when connected by said channel, sooner require it. (As amended by act approved May 25, 1907. In force July 1, 1907. L. 1907, p. 284.)

355. Expenses of Improvement—Special Assessments—General Tax.

13. The board of trustees shall have power to defray the expenses of any improvement made by it in the execution of the powers

hereby granted to such incorporation, by special assessment or by general taxation, or partly by special assessment and partly by general taxation, as they shall by ordinance prescribe. It shall constitute no objection to any special assessment; that the improvement for which the same is levied is partly outside the limits of such incorporation, but no special assessment shall be made upon property situated outside of such sanitary district, and in no case shall any property be assessed more than it will be benefited by the improvement for which the assessment is levied. The proceedings for making, levying, collecting and enforcing of any special assessment levied hereunder, shall be the same as nearly as may be as is prescribed by article nine of an act entitled "An act to provide for the incorporation of cities and villages," approved April 10, 1872. Whenever in said act the words "city council" are used, the same shall apply to the board of trustees constituted by this act, and the words applying to the city or its officers in that article shall be held [fol. 177] to apply to the corporation hereby created and to its officers.

356. Assessment—Installments—Interest.

14. When any assessment is made under this act, the ordinance authorizing such assessment may provide that it be divided into equal annual installments, not more than twenty in number, and fix the amount and time of payment of each installment, and that the installments shall bear interest at a rate not exceeding six per cent per annum, payable annually, from the date fixed in said ordinance, and the several installments and interests thereon may be collected and enforced, as they shall become due, in the manner provided for the enforcement of assessments under said Article 9. No more of any assessment need be returned or certified to the county collector than will show the amount due and unpaid at the time of such return, and no sale of any parcel of land for any installment of an assessment shall discharge the premises from any subsequent installment of the same or any other assessment. Any one or all of the installments may be paid any time after the assessment is confirmed, with accrued interest, if any, to the date of payment.

357. When Assessments Payable by Installments—Bonds May Be Issued.

15. Where any assessment is made payable in installments the board of trustees may issue bonds or certificates not exceeding in amount eighty per centum of the unpaid portion of such assessment at the date of the issue thereof, payable only out of such assessment, and bearing interest at a rate not exceeding the rate of interest upon the installments of such assessments. The board of trustees shall have the right to call in and pay off said bonds or certificates as fast as there is money received into the treasury from the assessment against which the same are issued, and all moneys received upon [fol. 178] such assessment shall be applied to the payment of said certificates or bonds until they are fully satisfied.

358. Private Property—How Taken for Improvement.

16. Whenever the board of trustees of any sanitary district shall pass an ordinance for the making of any improvement which such district is authorized to make, the making of which will require that private property should be taken or damaged, such district may cause compensation therefor to be ascertained, and condemn and acquire possession thereof in the same manner as nearly as may be as is provided in an act entitled "An act to provide for the exercise of the right of eminent domain," approved April 10, 1872: Provided, however, that proceedings to ascertain the compensation to be paid for taking or damaging private property shall in all cases, be instituted in the county where the property sought to be taken or damaged is situated; And, provided, that all damages to property whether determined by agreement or by final judgment of court shall be paid out of the annual district tax, prior to the payment of any other debt or obligation.

359. May Acquire Right of Way.

17. When it shall be necessary in making any improvements which any district is authorized by this act to make, to enter upon any public property or property held for public use, such district shall have the power so to do and may acquire the necessary right of way over such property held for public use in the same manner as is above provided for acquiring private property, and may enter upon, use, widen, deepen and improve any navigable or other waters, waterways, canal or lake: Provided, the public use thereof shall not be unnecessarily interrupted or interfered with, and that the same shall be restored to its former usefulness as soon as practicable: Provided, however, that no such district shall occupy any portion of [fol. 179] the Illinois and Michigan canal outside of the limits of the county in which such district is situated for the site of any such improvement, except to cross the same, and then only in such a way as not to impair the usefulness of said canal, or to the injury of the right of the State therein, and only under the direction and supervision of the canal commissioners: And, provided further, that no district shall be required to make any compensation for the use of so much of said canal as lies within the limits of the county in which said district is situated except for transportation purposes.

360. Special Assessment—Damage to Property and Cost of Acquiring.

18. In making any special assessment for any improvement which requires the taking or damaging of property, the cost of acquiring the right to damage or take such property may be estimated and included in the assessment as a part of the cost of making such improvement.

361. Liability of Sanitary District for Damages.

19. Every sanitary district shall be liable for all damages to real estate within or without such district which shall be overflowed or

otherwise damaged by reason of the construction, enlargement or use of any channel, ditch, drain, outlet or other improvement under the provisions of this act; and actions to recover such damages may be brought in the county where such real estate is situated, or in the county where such sanitary district is located, at the option of the party claiming to be injured. And in case judgment is rendered against such district for damage, the plaintiff shall also recover his reasonable attorneys' fees to be taxed as costs of suit: Provided, however, it shall appear on the hearing of plaintiff's motion to tax such attorney's fees, that the plaintiff notified the trustees of such district, in writing, at least 60 days before suit was commenced by leaving a copy of such notice with some one of the trustees of such [fol. 180] district, stating that he claims damages to the amount of — dollars by reason of (here insert the cause of damage) and intends to sue for the same: And, provided further, that the amount recovered shall be larger than the amount offered by said trustees (if anything) as a compromise for damages sustained. (As amended by act approved May 25, 1907. In force July 1, 1907. L. 1907, p. 284.)

361a. Inhabitant May Be Competent as Judge, Justice, or Juror.

19a. No person shall be an incompetent judge, justice or juror by reason of his being an inhabitant or freeholder in any sanitary district formed under the provisions hereof in any action in which such sanitary district may be a party in interest. (Added by act approved May 25, 1907. In force July 1, 1907. L. 1907, p. 284.)

362. Capacity of Channel or Outlet.

20. Any channel or outlet constructed under the provisions of this act which shall cause the discharge of sewage into or through any river or stream of water beyond or without the limits of the district constructing the same shall be of sufficient size and capacity to produce a continuous flow of water of at least two hundred cubic feet per minute for each one thousand of the population of the district drained thereby, and the same shall be kept and maintained of such size and in such condition that the water thereof shall be neither offensive or injurious to the health of any of the people of this State; and before any sewage shall be discharged into such channel or outlet, all garbage, dead animals and parts thereof, and other solids shall be taken therefrom, and said district shall, at the time any sewage is turned into or through any such channel or channels, turn into said channel or channels not less than twenty thousand cubic feet of water per minute for every one hundred [fol. 181] thousand inhabitants of said district, and shall thereafter maintain the flow of such quantity of water. (As amended by Act which became a law June 10, 1895. In force July 1, 1895: L. 1895, p. 168; Legal News Ed. p. 81.)

363. Sanitary District—Failure to Comply with Act—Remedy Penalty—Emergency Tax.

21. In case any sanitary district in this State formed under the provisions of this act shall introduce sewage into any river or stream of water, or natural or artificial water course, beyond or without the limits of such district, without conforming to the provisions of this act, or having introduced such sewage into such water course, shall fail to comply with any of the provisions of this act, an action to enforce compliance shall be brought by the Attorney General of this State in the courts of any county wherein such water course is situated, or he may authorize the State's Attorney of any such county to commence and prosecute such action in any such county: Provided, that nothing in this section contained shall be construed to prevent the prosecution of any action or proceedings by individuals or bodies corporate or politic against such district: And, provided further, that if any individual or the authorities of any municipal corporation shall file with the Attorney General a verified statement, in writing, setting forth wherein said sanitary district has failed to comply with any of the provisions of this act, it shall be the duty of the Attorney General forthwith to file in the Supreme Court of this State a petition for mandamus, setting forth wherein said sanitary district has failed to comply with the provisions of this act, and said court shall thereupon hear and determine such cause and proceed to enforce compliance with the provisions of this act, as in other cases of mandamus.

And, in order to comply with the provisions of this act, such sanitary district is hereby authorized and empowered to levy and collect such tax, as an emergency tax, upon the taxable property [fol. 182] of such sanitary district as may be necessary to carry into effect any order, judgment or decree of said court relating to the requisite flowage of water, capacity of the channel or outlet and the construction, maintenance and operation of movable bridges, as required by this act. (As amended by act approved May 15, 1897. In force July 1, 1897; L. 1897 p. 210; Legal News Ed. p. 76.)

364. Act—How Construed.

22. Nothing in this act contained shall be so construed as to constitute a contract or grant between the State of Illinois and any sanitary district formed under its provisions, or to prevent, debar or deprive the State of Illinois from, at any time in the future, altering, amending or repealing this act, or imposing any conditions, restrictions or requirements other, different or additional to any herein contained upon any sanitary district which may be formed hereunder.

365. Channel—How to Be Constructed.

23. If any channel is constructed under the provisions hereof by means of which any of the waters of Lake Michigan shall be caused to pass into the Desplaines or Illinois river such channel shall be

constructed of sufficient size and capacity to produce and maintain at all times a continuous flow of not less than 300,000 cubic feet of water per minute, and to be of a depth of not less than fourteen feet, and a current not exceeding three miles per hour, and if any portion of any such channel shall be cut through a territory with a rocky stratum where such rocky stratum is above a grade sufficient to produce a depth of water from Lake Michigan, of not less than eighteen feet, such portion of said channel shall have double the flowing capacity above provided for, and a width of not less than one hundred and sixty feet at the bottom capable of producing a depth of not less than eighteen feet of water. If the population of [fol. 183] the district draining into such channel shall at any time exceed 1,500,000 such channel shall be made and kept of such size and in such condition that it will produce and maintain at all times a continuous flow of not less than 20,000 cubic feet of water per minute for each 100,000 of the population of such district, at a current of not more than three miles per hour, and if at any time the general government shall improve the Desplaines or Illinois rivers, so that the same shall be capable of receiving a flow of 600,000 cubic feet of water per minute, or more, from said channel, and shall provide for the payment of all damages which any extra flow above 300,000 cubic feet of water per minute from such channel may cause to private property so as to save harmless the said district from all liability therefrom, then such sanitary district shall within one year thereafter, enlarge the entire channel leading into said Desplaines or Illinois rivers from said district to a sufficient size and capacity to produce and maintain a continuous flow throughout the same of not less than 600,000 cubic feet of water per minute with a current of not more than three miles per hour, and such channel shall be constructed upon such grade as to be capable of producing a depth of water not less than eighteen feet throughout said channel, and shall have a width of not less than one hundred and sixty feet at the bottom. In case a channel is constructed to the Desplaines river as contemplated in this section it shall be carried down the slope between Lockport and Joliet to the pool commonly known as the upper basin of sufficient width and depth to carry off the water the channel shall bring down from above. The district constructing a channel to carry water from Lake Michigan of any amount authorized by this act, may correct, modify and remove obstructions in the Desplaines and Illinois rivers wherever it shall be necessary so to do to prevent overflow or damage along said river, and shall remove the dams at Henry and Copperas Creek in the Illinois river, be- [fol. 184] fore any water shall be turned into the said channel. And the canal commissioners, if they shall find at any time that an additional supply of water has been added to either of said rivers, by any drainage district or districts, to maintain a depth of not less than six feet from any dam owned by the State, to and into the first lock of the Illinois and Michigan Canal at La Salle, without the aid of any such dam, at low water, then it shall be the duty of said canal commissioners to cause such dam or dams to be removed. This act

shall not be construed to authorize the injury or destruction of existing water power rights. (Canal Comrs. v. Sanitary District, 184 Ill. 597.)

366. Channel, When Completed—Control of.

24. When such channel shall be completed, and the water turned therein, to the amount of three hundred thousand cubic feet of water per minute, the same is hereby declared a navigable stream, and whenever the general government shall improve the Desplaines and Illinois rivers for navigation, to connect with this channel, said general government shall have full control over the same for navigation purposes, but not to interfere with its control for sanitary or drainage purposes.

367. May Permit Territories Outside to Drain, etc.

25. Any district formed hereunder shall have the right to permit territory lying outside its limits and within the same county to drain into and use any channel or drain made by it, upon such payments, terms and conditions as may be mutually agreed upon, and any district formed hereunder is hereby given full power and authority to contract for the right to use any drain or channel which may be made by any other sanitary district, upon such terms as may be mutually agreed upon, and to raise the money called for by any such contract in the same way and to the same extent as such district is authorized to raise money for any other corporate purposes: Pro- [fol. 185] vided, that where the united flow of any sanitary districts thus co-operating shall pass into any channel constructed within the limits of the county wherein such districts are located, and which passes into the Desplaines or Illinois rivers, such united flow shall in no case and at no time be less than 20,000 cubic feet of water per minute for each one hundred thousand of the aggregate of the population of the districts co-operating: Provided, nothing in this act shall in any wise be so construed as to diminish, impair or remove any right or rights of any city, village, township or corporation, body politic or individual situated on the Desplaines or Illinois rivers or their tributaries and within the valleys of the same to use the channel for drainage or otherwise not inconsistent with the rights of the district constructing the same as expressed in this act.

368. When City or Village Owns Waterworks, etc.

26. Whenever in any such sanitary district there shall be a city, incorporated town or village, which owns a system of waterworks and supplies water from a lake or other source which will be saved and preserved from sewage pollution, by the construction of the main channel, drain, ditch or outlet herein provided for, and the turning of the sewage of such city and district therein, and there shall be in such sanitary district any territory bordering on any such city, incorporated town or village within the limits of another city, incorporated town or village, which does not own any system of waterworks, at the time of the creation of such sanitary district, then

upon application by the corporate authorities of such latter named city, incorporated town or village the corporate authorities of such city, incorporated town or village having such system of waterworks shall furnish water at the boundary line between such municipalities by means of its waterworks to the corporate authorities asking for the same in such quantities as may be required to supply [fol. 186] consumers within said territory, at no greater price or charge than it charges and collects of consumers, within its limits for water furnished through meters in like large quantities.

369. When Channel Constructed—Commissioners to be appointed to inspect its work.

27. If any channel shall be constructed under the provisions of section 23 of this act, it shall be the duty of the trustees of such district, when such channel shall be completed, and before any water or sewage shall be admitted therein, to duly notify, in writing, the Governor of this State of such fact; and the Governor shall thereupon appoint three discreet persons as commissioners, one of whom shall be a resident of the city of Joliet, or between said city and the city of La Salle, and one a resident of the city of La Salle, or between said city and the city of Peoria, and one a resident of the city of Peoria, or between said city and the mouth of the Illinois river, to inspect said work. The said commissioners shall, within ten days after such appointment meet at the city of Chicago, and shall appoint a competent civil engineer, and they may employ such other assistance as they may require to expeditiously perform their duties. The said commission shall take as their datum line for the survey the datum established by the Illinois and Michigan Canal Trustees in 1847, and shall make such examination and surveys of Chicago river and of the channel or channels authorized by this act as shall enable them to ascertain whether said channel is of the character and capacity required by this act. And in case they shall find the work in all respects in accordance with the provisions of section 23, of this act, they shall so certify to the Governor, who shall thereupon authorize the water and sewage to be let into said channel. But in case said commissioners shall find said channel is not constructed in accordance with the provisions of this act, it shall be their [fol. 187] duty to file in any court of competent jurisdiction, on the chancery side thereof, in their name as such commissioners, a bill against said corporation, which bill shall set forth wherein said work is deficient and fails to comply with the provisions of this act; and said court shall thereupon issue an injunction without bond against said defendant, enjoining and restraining it from admitting water or sewage into said channel until the final order of the court. And in case said court, upon hearing, shall determine that said channel is not constructed in accordance with the provisions of this act, said injunction shall be continued until the provisions of this act shall have been fully complied with.

Such commissioners and engineers shall receive for their services ten dollars per day each, and their reasonable expenses and outlays for the time by them necessarily employed in the discharge of their

duties, which shall be paid to them from the State Treasury; and the said sanitary district shall reimburse the State for all expenses and disbursements on account of said commission.

If any channel is constructed under the provisions of this act which shall discharge the sewage of a population of more than 300,000 into or through any river beyond or without the limits of the district constructing it, the same shall be constructed in accordance with the provisions of section 23 of this act, and if any such channel receives its supply of water from any river or channel connecting with Lake Michigan it shall be construed as receiving its supply of waters from Lake Michigan.

An Act Concerning Police Power upon the Sanitary District of Chicago. (Approved June 16, 1893. In Force July 1, 1893. L. 1893, p. 96; Legal News Ed., p. 56.)

369a. Power to Appoint Force.

1. Be it enacted by the People of the State of Illinois, represented in the General Assembly, That the sanitary district of Chicago shall [fol. 188] have the right and power to appoint and support a police force, the members of which may have and exercise police powers over and within its right of way and for a distance of one and one-half miles on each side of its main drainage channel, such police powers as are conferred upon and exercised by the police of organized cities and villages; but such police force when acting within the limits of such city or village, shall act in aid of the regular police force of such city or village, and shall then be subject to the direction of its chief of police, city or village marshals or other head thereof.

An Act extending the powers of sanitary districts organized under an act entitled "An act to create sanitary district and to remove obstructions in the Desplaines and Illinois rivers," approved May 29, 1889, in force July 1, 1889, to enable such districts to improve certain navigable streams within or auxiliary to such district and to build bridges across such streams. (Approved May 13, 1901. In force July 1, 1901. L. 1901, p. 164; Legal News Ed., p. 94.)

369b. May Acquire Land, etc., by Purchase or under the Eminent Domain Laws.

1. Be it enacted by the People of the State of Illinois represented in the General Assembly: That any Sanitary district organized under an act entitled "An act to create Sanitary Districts and remove obstructions in the Des Plaines and Illinois rivers," approved May 29, 1889, in force July 1, 1889, which heretofore has or may hereafter use any navigable stream or river for a portion of its channel, or as an adjunct thereto or auxiliary to its main channel, may for the purpose of widening, deepening or improving the same, for purposes set forth in the act aforesaid, acquire by purchase, or under and pursuant to the eminent domain laws of this state, or otherwise,

sufficient land for the purpose of making such improvements by [fol. 189] widening and deepening said stream, as aforesaid.

369c. When District May Construct Bridge or Bridges.

2. That wherever it has or may become necessary by reason of the widening, deepening or improving of such river, to construct bridges to meet the altered or changed condition of such stream or river, such Sanitary District or districts may construct such bridge, or bridges as such improvement, heretofore made or hereafter to be made, may require.

369 D. Act, How Construed.

3. Nothing herein contained shall be construed as depriving any city, village or town, situated wholly or partly within the limits of said Sanitary District, of any power now exercised in the operation of said bridges; and any bridges built under the provisions of this act to supply or replace a public street or highway bridge, now or hereafter existing, shall, after the construction of said bridge, be operated and controlled for municipal purposes by said city, village or town within which it is located.

An act in relation to the Sanitary District of Chicago to enlarge the corporate limits of said district and to provide for the navigation of the channels created by such district and to construct dams, water-wheels and other works necessary to develop and render available the power arising from the water passing through its channels and to levy taxes therefor. (Approved May 14, 1903; in force July 1, 1903, L. 1903, p. 113; Legal News Ed., p. 92.)

369 E. Sanitary District of Chicago Extended.

1. Be it enacted by the people of the State of Illinois represented in the General Assembly: That the corporate limits of the sanitary district of Chicago, be, and the same are hereby extended so as to [fol. 190] embrace and include within the same, the territory and tracts of land situated in the County of Cook and State of Illinois, hereinafter described as follows, viz.:

First. The territory or tract of land bounded as follows: Beginning at the intersection of the county line between Lake and Cook counties, State of Illinois, with the west shore of Lake Michigan, running thence west along said county line to the northwest corner of Section three (3) Township forty-two (42) north, Range twelve (12), east of the third principal meridian; thence south to the southeast corner of Section thirty-three (33), Township forty-two (42) north, Range twelve (12) east of the third principal meridian; thence east to the northwest corner of section twelve (12) Township forty-one (41) north, Range twelve (12) east of the third principal meridian; thence south to the northwest corner of Section twenty-five (25), in said town and range; thence east to the northeast corner of the west half (½) of the west half (½) of said Section (twenty-five) 25; thence south to the southeast corner of the west half (½)

of the west half (½) of Section thirty-six (36) in said town and range; thence east to the northeast corner of the west half (½) of Section one (1), Township forty (40) north, Range twelve (12), east of the third principal meridian; thence south to the southeast corner of the west half (½) of Section thirteen (13) in said township and range; thence east to the southeast corner of Section thirteen (13) thence east, north, northwest and east along the present boundary line of said sanitary district of Chicago to the shore of Lake Michigan; thence northwesterly along the shore of Lake Michigan to the place of beginning.

Second. The territory or tract of land bounded as follows to-wit: Commencing at the northeast corner of Section three (3) in Township thirty-seven (37) north, Range thirteen (13) east of the third principal meridian; running thence south to the southwest corner [fol. 191] of section eleven (11), township thirty-six (36) north, range thirteen (13) east of the third principal meridian; thence east and south along the boundary lines of Section fourteen (14) in said Township thirty-six (36) to the southeast corner of said Section fourteen (14), thence east to the southeast corner of Section seventeen (17) in Township thirty-six (36) north, Range fifteen (15), east of the third principal meridian; thence north along the east boundary line of the State of Illinois to its intersection with the shore of Lake Michigan, thence along the shore of Lake Michigan to the south boundary line of the present sanitary district of Chicago; thence west along the present south boundary line of the said sanitary district of Chicago to the place of beginning.

369 F. Drainage of Added Territory—Use Calumet Feeder—Illinois and Michigan Canal—Connection with Land for Use of Canal Commissioners.

2. The board of trustees of said sanitary district shall have the right to provide for the drainage of the additional territory added to said sanitary district by this act by laying out, establishing, constructng and maintaining one or more channels, drains, ditches and outlets for carrying off and deposing of the drainage (including the sewage) of such district, together with such adjuncts and additions thereto as may be necessary or proper to cause such channels or outlets to accomplish the end for which they are designed in a satisfactory manner and shall have the right to use what is known as the "Calumet feeder" of the Illinois and Michigan canal and lands adjacent to such feeder belonging to the State of Illinois for the site of any such channel, within the limits of the county in which such district is situated, in such manner as said district may elect, and shall also have the right to construct a channel across said Illinois and Michigan canal, without being required to restore said Illinois and Michigan canal or said feeder to its former usefulness. If, [fol. 192] by reason of said abandonment, a stagnant stream or pool of water shall remain upon the deposits of Chicago sewage, accumulated in said Illinois and Michigan Canal by reason of its years of usefulness by the city of Chicago as a sewage outlet, said

sanitary district shall fill up said canal to a depth sufficient to remove said condition and prevent the spread of pestilence and disease throughout the territory in which said Illinois and Michigan Canal is abandoned; and the other powers and jurisdiction of said sanitary district of Chicago over and in connection with such added territory shall be the same as that vested in it over the territory included within the limits of said sanitary district as originally organized. Before said Calumet channel is connected with the present main sanitary channel, gates of suitable pattern for shutting off the flow of water into said Calumet channel shall be installed at or near the connection of said Calumet channel with the Calumet river and forever maintained for use in case of an emergency, and for the protection of the property and lives of residents of the Illinois valley, and shall maintain the same proportion of dilution of sewage through such auxilliary channels as it may construct and join to its main channel as is now required by the act creating said sanitary district: Provided however, that before any such channel is constructed across said Illinois and Michigan Canal, or the navigation of said canal in any manner interfered with, said sanitary district of Chicago shall connect its present main channel from the controlling works at Lockport with the upper basin of the Illinois and Michigan Canal at Joliet by a channel of a depth of not less than ten (10) feet and a width of not less than one hundred and sixty (160) feet through its entire length, in which channel so to be constructed said sanitary district shall provide and construct a lock or locks of the size of at least twenty-two (22) feet in width by one hundred and thirty (130) feet in length between mitre sills, connecting upper [fol. 193] and lower levels, and provide suitable protection for water craft in using said locks and channel. Said locks shall be constructed of the most approved pattern of their size, and be perfectly safe for use and be equipped with machinery to operate the same; and if only one lock is constructed it shall be provided with double gates to prevent accident, and said sanitary district shall forever maintain and operate the same. Provided, further, that said sanitary district shall furnish and provide at said lock a site of the dimensions of at least twenty by thirty feet upon which the State through the Canal Commissioners shall have the right to erect a suitable office building and keep an agent therein, and the Canal Commissioners shall have such authority in and about said lock as is necessary to enforce the rules and regulations prescribed by them pertaining to and governing navigation on the Illinois and Michigan Canal: Provided, further: That said sanitary district shall furnish, free of all expense, for the perpetual use of the Canal Commissioners, at some point in the township of Lockport to be agreed upon by the Canal Commissioners and the sanitary district trustees, a strip or parcel of land bordering upon said sanitary channel, eight hundred (800) feet in length and one hundred and thirty (130) feet in width, filling the same to a suitable depth to provide suitable roadways for approaches, whereon may be located, constructed and operated docks, shops, barns and other buildings controlled by the Canal Commis-

sioners and used in connection with the operation of the Illinois and Michigan Canal.

369 G. Navigation on Sanitary District Channels

3. Said sanitary district shall permit all water craft navigating or proposing to navigate said Illinois and Michigan Canal to navigate the water of all said channels of said sanitary district promptly, without delay and without payment of any tolls or lockage charges for so navigating in said channels. The rules of the United States government now in force, regulating navigation on the Chicago [fol. 194] river shall govern navigation on the channels of said sanitary district of Chicago; Provided however, that the speed of all vessels while passing through the earth sections shall not exceed eight (8) miles per hour.

369 H. No Special Tax or Assessment for Work Heretofore Done on Main Channel Added Territory.

4. Said sanitary district of Chicago, shall have no power to levy and collect any special assessment or special tax upon any part of said added territory to defray or pay any part of the cost, either of the work heretofore done by said sanitary district or any main channel hereafter to be constructed in said added territory.

369 I. Authority to Develop Water Power.

5. That the said sanitary district of Chicago is hereby authorized to construct all such dams, waterwheels and other works north of the upper basin of the Illinois and Michigan Canal as may be necessary or appropriate to develop and render available the power arising from the water passing through its main channel and any anuxiliary channels now or hereafter constructed by said district.

369 J. How Such Power May Be Utilized.

6. That the power made available by the works constructed under the provisions of this act shall be converted into electrical energy and shall be transmitted to the various cities, villages and towns within said sanitary district or adjacent to the main channel of said sanitary district and may be used in the lighting of said cities, villages and towns, or parts thereof, or for the operation of pumping plants or machinery used for municipal purposes or for public service, or may be disposed of to any other person or corporation, upon such terms and conditions as may be agreed to by the said sanitary district; Provided, however, that it shall be the duty [fol. 195] of said sanitary district to utilize so much of said power as may be required for that purpose to operate the pumping stations, bridges and other machinery of said sanitary district.

369 K. Authority to Levy Tax.

7. That for the purpose of meeting the expenditures arising from the exercise of the powers conferred by sections five and six of this act upon the said sanitary district, the said sanitary district of Chi-

cago is hereby authorized to levy and collect in each year, for a period of three years (in addition to the taxes which said district is now by law authorized to levy and collect) a tax of not exceeding one-fourth of one per cent of the value of the taxable property within the corporate limits of said district, as the same shall be assessed and equalized for the State and county taxes of the year in which the levy is made; Provided, further, that the county clerk, in extending said one-fourth of one per cent tax upon the taxable property within said sanitary district, shall not in any event reduce the same, but in that rspect said one-fourth of one per cent shall not be subject to the provisions of an act entitled, "An act concerning the levy and extension of taxes," approved May 9, 1901.

369 L. Comply with Acts of Congress as to Illinois and Michigan Canal.

8. The said sanitary district shall at the expense of said district, in all respects comply with the provisions of the acts of Congress of March 22, 1822, and March 2, 1827, as construed by the courts of last resort of the State of Illinois and of the United States, in relation to the Illinois and Michigan Canal, so far as it affects that portion of the Illinois and Michigan Canal vacated or abandoned by the terms of this act.

[fol. 196] 369 M. Petition for Question to be Submitted—Election.

9. If within sixty (60) days after the passage of this act a petition signed by not less than three per cent of the legal voters of the territory within the limits of the sanitary district of Chicago, as the same are enlarged by the terms of this act, praying that the question of the adoption of this act shall be submitted to a vote of the electors of the territory within the said limits of the said sanitary district of Chicago, shall be filed with the clerk of said sanitary district, then and in such case the question of the adoption of this act shall be submitted to a vote of the said electors as in said petition prayed, at the general election to be held in the County of Cook in November 1904, and in such case this act shall not be in force unless a majority of the votes cast at said election upon the question of the adoption of this act shall be in favor of the adoption thereof. It shall be the duty of the election officers having charge of the preparation of the ballots and the giving of the notices of election and of the counting, canvassing and making return of the ballots to take all necessary steps and do all necessary acts to cause the said question of the adoption of this act to be submitted to a vote as hereinbefore provided, and to cause the result of such election to be canvassed and certified, as provided by law in other similar cases.

[fol. 198] EXHIBIT "C" TO ANSWER

War Department, Washington

March 14, 1907.

In the Matter of the Application of THE SANITARY DISTRICT OF CHICAGO to Reverse the Flow of the Calumet River

This application is made under Section 10 of the act of March 3, 1899 (30 Stat. L., 1151), which provides as follows:

"Sec. 10. That the creation of any obstruction, not affirmatively authorized by Congress, to the navigable capacity of any of the waters of the United States is hereby prohibited; and it shall not be lawful to build or commence the building of any wharf, pier, dolphin, boom, weir, breakwater, bulkhead, jetty or other structures in any port, roadstead, haven, harbor, canal, navigable river, or other water of the United States, outside established harbor lines, or where no harbor lines have been established, except on plans recommended by the Chief of Engineers and authorized by the Secretary of War; and it shall not be lawful to excavate or fill or in any manner to alter or modify the course, location, condition, or capacity of, any port, roadstead, haven, harbor, canal, lake, harbor of refuge, or inclosure within the limits of any breakwater, or of the channel of any navigable water of the United States, unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same."

The application of the Sanitary District is for leave to reverse the flow in the Calumet River in such a way as to make the water to flow out of the lake instead of to flow into it and to discharge the water from the Calumet River into the Drainage Canal. The Chief of Engineers was at first of opinion that such a change in the flow of the river *it* was not within the power of the Chief of Engineers to recommend, or within the power of the Secretary of War to permit. This expression of opinion as to the construction of the stat-
[fol. 199] ute was submitted to the Judge Advocate General, who holds that Section 10, as quoted above, applies to this case and that it is one in which work could be allowed under the recommendation of the Chief of Engineers and the permission of the Secretary of War. Upon the construction of the Judge Advocate General I requested the Chief of Engineers to make his recommendation, which he has done as follows:

"February 23, 1907.

1. Respectfully returned to the Secretary of War.

2. The subject of the abstraction of water from Lake Michigan has been elaborately investigated by the Lake Survey Office at Detroit, and the results are published in the annual reports of the Chief

of Engineers for the years 1900, 1902 and 1904. The international Waterways Commission has also given it careful consideration, and its conclusions are set forth in report of January 4, 1907, printed as War Department Document No. 293.

3. In my opinion, this abstraction will undoubtedly lower the levels of all the waters of the Great Lakes, except those of Lake Superior, and thus diminish the navigable capacity and depth of the various channels and harbors which have been deepened and improved under authority of Congress.

4. Leaving out Lake Superior, there are more than 100 works of river and harbor improvements on the Great Lakes and their connecting waters, for which appropriations aggregating more than $80,000,000 have been made. The application of this vast sum has resulted in securing and maintaining specified depths and widths of channel, which Congress has decided to be required for the accommodation of the traffic using those waters.

5. To diminish these depths even to a slight extent, would not only prove a serious injury to the traffc, but would practically undo the work which has been accomplished by Congressional direction, and necessitate the expenditure of further large sums of money for restoration. Any project that tends, in a measure, to annul or reverse the orders of Congress, as expressed in the various river and harbor acts appropriating funds for improving the harbors and [fol. 200] channels connecting with the Great Lakes, should meet the disfavor of the Department, unless it has been sanctioned by that body. In my judgment, such a project is the one under consideration, and for this reason I am unwilling to recommend favorable action thereon, assuming that the Department is empowered to take such action, as is held by the Judge Advocate General.

A. Mackenzie, Brig. Gen., Chief of Engineers, U. S. Army."

It is quite evident from the reading of the statute that Congress intended in this statute, as in many others, to give the Chief of Engineers authority, independent of the Secretary of War, in reaching a conclusion as to the wisdom and propriety of granting a permit under the section, and that unless the Chief of Engineers shall recommend the granting of the permit, the Secretary of War is without power to give the requested authority. It follows, therefore, that the application must be denied whatever my view of the case.

The decision of the Chief of Engineers and its final character has made it unnecessary for me to consider the merits of the question, but I may say this much, that the application for a change in the Calumet River is to be made the basis for the withdrawal of a large amount of water from Lake Michigan and that all interested in the enormous lake traffic view the settlement of the question with grave apprehension. Added to this, is the international complication which is likely to arise in the threatened lowering of the lake level in the ports and harbors and canals of Canada. On the other hand, it is maintained with great emphasis and elaboration of detail

that the change in the Calumet River, is essential to the healthful sanitation of Chicago, and that the threatened injury to navigation is so small as to be negligible.

Between too such great interests, the decision must be affected more or less by large public policy and expediency, and while I [fol. 201] agree in the construction of the Judge Advocate General that the issue is left by statutes to the recommendation of the Chief of Engineers and the concurrent decision of the Secretary of War, it may be fortunate that circumstances now require submission of this question of capital and national importance to the Congress of the United States.

Wm. H. Taft, Secretary of War.

(Reprinted from proceedings of Board of Trustees, March 27, 1907, pages 211-12.)

[fol. 202] EXHIBIT "D" TO ANSWER

"War Department,
Washington, September 11, 1907.

SIR: Referring to your letter of 2nd instant, in which you request approval of proposed drainage channel to connect Lake Michigan at Wilmette, Ill., with the North Branch of the Chicago River; also permission to construct a pile crib in Lake Michigan at mouth of same, and to deposit filling within the limits of such crib, I beg to inform you that the War Department will interpose no objection to the project as set forth in your letter and indicated on drawing submitted, provided the following conditions are complied with:

1. That the pier constructions, the filling behind the same, and the excavation of the proposed channel shall be done subject to the supervision and approval of the local officer of the Corps of Engineers, U. S. Army, at Chicago, so far as to see that the work authorized is not exceeded;

2. That the total diversion of water from Lake Michigan through the Chicago River into the Illinois River shall be no greater than already authorized by past War department permits;

3. That the work shall be commenced before December 31, 1908, and completed within five years thereafter.

Very respectfully, Robert Shaw Oliver, Acting Secretary of War. G. M. Wisner, Esq., Chief Engineer the Sanitary District of Chicago, American Trust Building, Chicago, Illinois."

[fol. 203] EXHIBIT E TO ANSWER

Permit

War Department,
Washington, June 30, 1910.

SIR: Referring to your application of the 27th instant on behalf of the Board of Trustees of The Sanitary District of Chicago to open a channel from the Calumet River to its existing Main Channel so as to substitute two routes instead of one between Lake Michigan and its canal, I have the honor to advise you to the following effect:

It appears from the records of the Department that by an instrument executed May 8, 1899, The Sanitary District of Chicago was given permission to connect its Drainage Canal with the South Branch of the Chicago River at Robey Street, in the City of Chicago, and to divert the waters of Lake Michigan through the Chicago River into said canal, subject to certain specified conditions designed to limit the amount of such diversion and in other ways to protect the public interest. The permission so granted was subsequently modified at various times, and by an instrument executed December 5, 1901, the amount of flow was fixed at not exceeding 250,000 cubic feet per minute, equivalent to 4,167 cubic feet per second, which is the present rate allowed. At the time the original permit was given a connection with the Calumet River was not mentioned but if it had been it is probable that a connection with that river as well as with the Chicago River would have been allowed.

So long as the water-flow remains unchanged there seems to be no special objections to its extension to both rivers instead of confining it to a single one, especially since if the new (Calumet) route be developed later to a navigable state the double route will be ad-
[fol. 204] vantageous to navigation interests. Accordingly, in view of the favorable recommendation of the Chief of Engineers and of the consent thereto by the Attorney General, under the conditions hereinafter prescribed, the Department hereby modifies the existing permission so as to allow the division of the already permitted water-flow in such manner as to reach the Sanitary District Canal by way of the Calumet River and a connecting channel, as well as by way of its present route through the Chicago River, subject to all pertinent conditions of the existing permissions and to other express conditions, as follows:

(a) That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of The Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

(b) That if at any time it become apparent that the current created by such drainage work in the Calumet, as well as Chicago rivers, be unreasonably obstructive to navigation, or injurious to property, the Secretary of War reserves the right to close the discharge through

said channel or rivers, or to modify it to such an extent as may be demanded by navigation and property interests along said rivers.

(c) That The Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in the Calumet as well as Chicago river.

(d) That the amount of water withdrawn from Lake Michigan, through the Chicago and Calumet rivers together, shall not exceed the total amount of 250,000 cubic feet per minute (4,167 cubic feet per second) already authorized to be withdrawn through the Chicago River alone.

(e) That the permission herein given shall be subject to such [fol. 205] modification as in the opinion of the Secretary of War the public interests may from time to time require.

(f) That this permission shall in nowise affect or in any manner be used in the friendly suit now pending in the Circuit Court of the United States for the Northern District of Illinois brought by the United States of America against the Sanitary District of Chicago, to determine the right of the said Sanitary District to divert from Lake Michigan for sanitary purposes an amount of water in excess of that now being diverted, without having first obtained a permit from the Secretary of War.

(g) That the War Department shall have free access at all times to the waterflow records of The Sanitary District of Chicago and free access also to the regulating works and all other parts of its canals for the purpose of checking records or making water-flow measurements.

(h) That the plans for the proposed work shall be submitted to and approved by the Chief of Engineers and the Secretary of War.

(i) That the work shall be subject to the supervision and approval of the Engineers Officer of the United States Army in charge of the locality.

Very respectfully, Robert Shaw Oliver, Acting Secretary of War. Mr. George M. Wisner, Chief Engineer Sanitary District of Chicago, Chicago, Ill.

(Reprinted from the proceedings of the Board of Trustees, November 2, 1911, pages 1323-25.)

[fol. 206] EXHIBIT "F" TO ANSWER

Memorial to Congress on the Subject of the Illinois and Michigan Canal

(Laws Extra Session, 1826, p. 97)

To the Honorable the Senate and House of Representatives of the United States of America in Congress assembled:

The memorial of the General Assembly of the State of Illinois respectfully represents that the construction of a canal uniting the waters of Lake Michigan with the Illinois river, will form an important addition to the connecting links in the chain of internal navigation, which will effectually secure the indissoluble union of the confederate members of this great and powerful Republic. By the completion of this great and valuable work, the connection between the north and the south, the east and the west, would be strengthened by the ties of commercial intercourse and social neighborhood, and the union of the states might bid defiance to internal commotion, sectional jealousy and foreign invasion. All the states of the Union would then feel the most powerful motives to resist every attempt at dissolution. To effect so great and desirable an object, your memorialists believe to be of sufficient importance to engage the attention and awaken the munificent patronage of a government whose principle of action is the promotion of the general welfare. Your memorialists are sensibly alive to the spirit of improvement that manifests itself in almost every section of our extensive country, and would fain lend a helping hand in so great and good a cause; their situation, however, forbids their doing much, without the aid of the federal government; into whose treasury almost all the funds whether brought hither by emigrants or earned by the industry of their citizens, are paid for the purchase of the public lands. While this state [fol. 207] of things shall continue and the money thus paid into the treasury of the Union is taken out of our State, our people will not be able to engage in the glorious work of improving our common country. Ought the people of this State to stand by with folded arms and behold the great work of internal improvement progress in other states without making an effort to improve their own conditions, and at the same time advance the interest of our beloved country? A condition thus paralyzed, is at war, not only with our interests, but with the best feelings of our hearts. Did this State possess the public domain lying within its bounds, as in the case with the older members of this confederacy, your memorialists would not appear before your honorable body to solicit aid in this important work. If, as your memorialists believe, the construction of this canal would be highly beneficial to the Union at large; if the receipts into the treasury of the United States would be augmented by the increased sales of public lands; and if the interest of this State would be also advanced thereby; is it unreasonable to apply to a paternal government for assistance in the promotion of such beneficial ends? It is un-

necessary for your memorialists to enlarge on the great advantages of this canal to the Union, in the facilities to be afforded in the event of a war with either the Indian tribes inhabiting our frontier, or the British nation. Your honorable body is aware that this State is situated on the borders of an Indian country, filled with numerous and powerful tribes of the sons of the forest. If our country should be again engaged in war, the saving of expense in the transportation of munitions of war, would alone defray the expense of the contemplated canal, and justify the United States in making a liberal appropriation for its construction. Your memorialists do not, however, ask your honorable body to appropriate money out of the treasury to aid them in this work; they only ask for a tract of land, [fol. 208] through which the contemplated canal may pass, and which, for a series of years, will be wholly unproductive to the government unless the canal shall be commenced under auspices favorable to its completion; in which event all the land in the vicinity would immediately become available to the United States. Your memorialists sincerely believe that a liberal appropriation of land for this object, would, even in a pecuniary point of view be of immense importance to the treasury of the Union. The public lands in the vicinity would not only sell, but at a considerable advance upon the minimum price. Should this opinion be correct (and does not experience justify it?) the United States would be gainers by the proposed donation to the State. Your memorialists further state that at their last session, they passed an act of incorporation, upon very liberal terms, authorizing a company to construct the projected canal; but the remoteness of the country from the residence of capitalists, has prevented them from engaging in the work. At their present session, your memorialists have repealed the charter; and their only hope of soon beginning the work depends upon the liberality of your honorable body. Your memorialists have caused the route to be explored and estimates to be made of the probable expense of the work; from which it appears that the cost of constructing the canal will not be less than $600,000 and may possibly amount to $700,000. To the end, therefore, that your memorialists may be enabled to commence and complete this great and useful work, we pray your honorable body to grant to this State the respective townships of land through which the contemplated canal may pass; the avails of which, to be appropriated exclusively, to the construction of said canal, upon such terms and conditions as to your honorable body may seem proper.

[fol. 209] EXHIBIT "G" TO ANSWER

"An Ordinance for Cleansing the Chicago River and Appropriating the Proceeds of Two Hundred and Fifty Bonds Therefor.

Section 1. Be it ordained by the Common Council of the City of Chicago (June 5, 1865), That the plan of the board of public works for cleansing the Chicago River and its branches by cutting down

the summit of the Illinois and Michigan Canal below the level of Lake Michigan so as to draw from it at a low stage of water in the lake not less than twenty-four thousand (24,000) cubic feet of water per minute, is hereby approved, and said board are hereby authorized to execute said work.

Section 2. That the board of public works are hereby authorized and empowered for the purpose of prosecuting the work described in the previous section, to make any contract necessary to carry into effect such purpose with the trustees of the Illinois and Michigan Canal, in conformity with and subject to the general provisions of the city charter.

Section 3. That as a temporary expedient for cleansing the South Branch of the Chicago River, the said board are hereby authorized and empowered to contract with the said trustees for the pumping from the river into the canal, by the hydraulic works at Bridgeport, and discharging through the canal of such amount of water as shall be found necessary and practicable for such purpose.

Section 4. That for the purpose of carrying out the improvement specified in the foregoing sections, the board of public works be and they are hereby authorized to issue 250 bonds of the denomination of $1,000 each, to be dated July 1, 1865, and payable in New York, twenty-five years after the date thereof, with coupons for interest, at the rate of seven per centum per annum, payable semi-annually in New York; the said bonds to be issued in conformity with the provisions of an act of the General Assembly of the State of Illinois, approved February 15, 1865, and entitled 'An act to amend an act entitled an act to reduce the charter of the City of Chicago, and the several acts amendatory thereof, into one act, and to revise the same,' approved February 13, 1863."

Application of the Sanitary District for the Improvement of the Chicago River

Chicago, June 16, 1896.

To the Honorable Daniel S. Lamont, Secretary of War, Washington, D. C.

DEAR SIR: The work of The Sanitary District of Chicago has progressed so far that it is now necessary for us to enter upon that which must be done in the Chicago River to make available the artificial channel which we have under construction from Robey Street, Chicago, to Lockport in Will County, twenty-eight miles distant.

Our connection with Lake Michigan must be through the Chicago river with the West Fork of the South Branch of which we make a junction at Robey Street. We send herewith a map showing in a

12 Widening River at Loomis St. (Deering) Bridge.
13 Widening River and new bridge at Ashland Ave.

NOTE.

The above map is a correct copy of a map, which accompanied the letter of R.A. Lidstone, President of the Sanitary District of Chicago, of June 8, 1911 to the Hon. Dewitt S. Lamont, Secretary of War of the United States, asking permission to make improvements on the Chicago River.

R.E. Armstrong
Chief Draftsman

general way our plans for improving the Chicago River by widening and deepening at the points indicated thereon by red hatchings and by figures which refer to explanation, given in the legend on the map. It is desired to so correct and regularize the cross section of the river as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of one and one-quarter miles per hour. The cross section necessary to accomplish this can be obtained throughout the greater part of the distance between Monroe Street and Robey Street, by dredging the river to a depth of 20 ft. at mid stream, with 12 ft. at dock lines and a uniform slope away from docks of one foot in five, so that the full depth would be reached forty feet from the dock lines; but there are places so narrow that this cross section can only be obtained by widening the river; and again the depth to be ob-
[fol. 211] tained in the vicinity of Van Buren Street is limited by the height of the crown of the tunnel. To obviate this difficulty it is purposed to secure the requisite cross section by constructing a by-pass to the west of the bridges at Adams, Jackson and Van Buren Streets, as indicated. We ask your permission to proceed with the work upon the lines indicated and so far as is consistent with propriety the co-operation of the United States Engineering Department.

Awaiting your favorable reply, and holding ourselves ready to respond to any call from you for fuller information as to our plans, I am

Yours respectfully, (Signed) B. A. Eckhart, President.

A copy of the above letter is found at Page 297 of the Clerk's Copy Letter Book "C," being letter book from September 20, 1895, to January 11, 1897.

(Here follows Exhibit H to Answer, marked side folio page 212)

[fol. 213] EXHIBIT I TO ANSWER

Permit for the Improvement of the Chicago River

(Permit of July 3rd, 1896)

Improvement of the Chicago River

July 3, 1896.

SIR: I have the honor to acknowledge the receipt of your letter of 16th ultimo, requesting permission to make certain changes in the capacity of the channel of the Chicago River for drainage purposes at points indicated on the map accompanying the application, and in reply beg to say that upon investigation it is found that the permission requested can be granted upon the following conditions:

1. That while the general plan is approved, the Sanitary District of Chicago must furnish plans in triplicate on an enlarged scale

showing each proposed new bridge, each by-pass and each new dock or wharf proposed to be built, in order that the Secretary of War may act intelligently in each case.

2. That this authority shall not be interpreted as approval of the plans of the Sanitary District of Chicago to introduce a current into Chicago River. This latter proposition must hereafter be submitted for consideration.

3. That it will not cover obstructions to navigation by reason of this work while in progress or when completed.

4. That the United States shall not be put to expense by reason of this work.

5. That this authority will expire by limitation in two years from date unless extended.

Very respectfully, (Signed) Joseph B. Doe, Acting Secretary of War. B. A. Eckhart, Esq., President the Sanitary District of Chicago, Rialto Building, Chicago, Ill.

[fol. 214] EXHIBIT J TO ANSWER

The Sanitary District of Chicago

Security Building

Chicago, April 26, 1900.

To the Honorable the Secretary of War.

SIR: The Sanitary District of Chicago, a municipal corporation organized and existing under the laws of the State of Illinois, respectfully represents that, by the laws of the State of Illinois and the charter of this petitioner, it is authorized to enter upon, widen, deepen and otherwise improve any navigable stream, river or other water-way. That in pursuance of the power conferred upon it by the statutes of the State of Illinios, and in the performance of the duties enjoined upon it by the act of the Legislature authorizing its creation, and under which it is acting, it has been determined to improve the Chicago River by widening and deepening the same and to the end that such action on the part of your petitioner may be conformable to law and the statutes of the United States in that behalf, it hereby makes application for permission to make the changes, alterations and improvements in said Chicago River from or near Lake Street in the City of Chicago to or near Ashland Avenue in the City of Chicago, said work to conform to the plan and specifications as follows:

(a) A map herewith exhibits the existing boundaries of that part of the South Branch of the Chicago River which it purposes and desires to improve.

(b) The work to be done contemplates widening the river to a width of two hundred (200) feet between dock lines, except in so far as bridge abutments may project into the stream outside of the new [fol. 215] dock lines; said widening in all cases to be made with a view of improving the navigability of the stream.

(c) The work to be so done as to ultimately permit excavation of the river bed to a depth of thirty (30) feet below water surface throughout the central portion of the stream.

(d) The widening of the river is to be so disposed that the effect will be to produce a straighter channel than now exists and, furthermore, to result in a continuous dock line having straighter alignment and being better disposed for navigation than the docks which now exist.

(e) The work to be done is to be prosecuted progressively as to time. The rate of progress being limited by the rapidity with which right of way may be acquired and the resources for the execution of the work to be made available. The modification and alteration of said river as above indicated will greatly benefit navigation in said river. Your petitioner, therefore, respectfully requests that the plan of improvement as above outlined be approved by you.

Awaiting as early a reply as practicable under the circumstances, your petitioner has the honor, to be.

Very respectfully yours, The Sanitary District of Chicago, by William Boldenweck, President. Attest: Joseph H. Haas, Clerk.

[fol. 216] EXHIBIT J-1 TO ANSWER

Chicago, June 7, 1900.

To the Honorable, the Secretary of War.

SIR: Under date of April 26, 1900, the Sanitary District of Chicago had the honor to address a communication to you containing an outline of the proposed improvement of a portion of the South Branch of the Chicago River. Accompanying the letter was a map showing the location of the South Branch of the Chicago River, the bridges spanning said river and, also, the width of the stream along the entire course of the South Branch of the river. Since that date the Sanitary District of Chicago passed an ordinance for the improvement of the South Branch of the Chicago River from the south line of Twelfth Street to the east line of Ashland Avenue, so as to make said South Branch, between the lines aforesaid, of a uniform width of two hundred (200) feet; the work to be done so as to ultimately permit excavation of the river bed to a depth of thirty (30) feet below water surface throughout the central of said stream, in accordance with the plans adopted by the Board of Trustees of the Sanitary District of Chicago, a copy of which plans is hereto annexed. The

ordinance referred to being marked Exhibit "A," with this letter; and the maps showing the plans of the proposed improvement being marked Exhibit "B." The maps are in two sections, known respectively as No. 2 and No. 3.

The Sanitary District of Chicago is a municipal corporation, organized and existing under the laws of the State of Illinois and by the laws of said State and the charter of said Sanitary District, it is authorized to enter upon, deepen, widen and otherwise improve [fols. 217 & 218] any navigable stream, river, or other water-way; and that in pursuance of the power conferred upon it by the statutes of the State of Illinois and in performance of the duties enjoyed upon it by the act of the legislature authorizing its creation, and under which it is acting, it determined upon said plans outlined in the enclosed ordinance and further illustrated by the maps hereto annexed; and the said Sanitary District, in compliance with the Statutes of the United States, hereby makes application to you for permission to make the changes, alterations and improvements in said South Branch of the Chicago River, from the south line of Twelfth Street to the east line of Ashland Avenue.

Awaiting as early a reply as practicable under the circumstances, your petitioner has the honor to be,

Very respectfully yours, The Sanitary District of Chicago, by William Boldenweck, President. Attest: Joseph F. Haas, Clerk.

Notice of Motion to Strike from Answer—Filed February 28, 1914

To Edmund D. Adcock, Karpen Building, and Alfred S. Austrian, American Trust Building, Chicago, Solicitors for Defendant:

Please take notice that on Saturday, February 28th, 1914, at the opening of court on that day, or as soon thereafter as counsel can be heard, before Honorable Kenesaw M. Landis, Judge of the United States District Court for the Northern District of Illinois, at his court room in the city of Chicago, I shall move to strike from the answer herein each of the allegations in paragraphs 20–46, inclusive.

And for grounds for this motion, the complainant states as to each of said allegations, that it is not responsive to any averment in the bill of complaint; that it sets forth affirmative matters not proper to be proved as a defense in this case, and that evidence offered at the hearing in support thereof would necessarily be excluded as incompetent, irrelevant, immaterial and not pertinent to any issue in this case.

The complainant, at the time above stated, will enter said motion and ask to have the same set for hearing in accordance with Equity Rule thirty-three.

James H. Wilkerson, United States Attorney.

Carpenter, Judge. 18 June, 1923.

[fol. 231] IN THE DISTRICT COURT OF THE UNITED STATES FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

OPINION—Filed June 18, 1923

CARPENTER, District Judge (orally): It is needless to say that this litigation is of vital interest to the people of the State of Illinois. It was started nearly fifteen years ago by bill filed in behalf of the United States of America against the Sanitary District of Chicago to restrain the defendant from diverting from the waters of Lake Michigan in excess of approximately 4,500 feet per second.

The parties used the better part of six years in putting in the proof. The matter was then presented with appropriate briefs to my distinguished colleague, Judge Landis, for final determination. Judge Landis kept the matter under advisement for another six years, moved undoubtedly by the thought that the State of Illinois was being benefitted all of the time by the withdrawal of 10,000

cubic feet a second by the defendant, and that the Government was not in any way actually harmed.

On June 19th, 1920, Judge Landis rendered an oral opinion, finding in effect that the withdrawal in excess of 4,167 cubic feet a second by the Sanitary District of Chicago was without authority of law; that the withdrawals then being made reduced the level [fol. 232] of Lake Michigan, and other of the navigable waters of the United States, to such an extent as to be an interference with navigation; that the Secretary of War, acting under Congressional powers, had never given his consent to such excessive withdrawals; that the diversion by the Sanitary District was therefore unlawful, and an injunction should issue.

A motion was made thereafter not for a reconsideration of the findings of the Court, but for the purpose of settling the terms of the final decree.

Attorneys for the Sanitary District urged the evidence showed clearly that by the construction of weirs and other compensating works at a relatively small expense, the Government could restore the various water levels which had been reduced by the flow into the drainage canal. They also urged that the State of Illinois, by appropriate legislation, had authorized the Sanitary District to agree with the United States Government to stand the cost of such weirs and compensating works and their annual maintenance, and strenuously urged upon the Court that as a condition to the entry of any injunction, the plaintiff Government should agree to erect and maintain such works at the expense of the defendant.

Counsel for the Drainage District have also urged upon the Court at this time to reconsider entirely the case upon the evidence presented.

[fol. 233] This Court is very much disinclined to interfere with the judgment of Judge Landis. At least it is entitled to the weight that would be given to the report of a Master in Chancery or Special Commissioner. In addition, this Court has gone over the entire record, and is able to say that it agrees with Judge Landis in every respect, although from a legal standpoint, with some reluctance.

It is not necessary to go into the duties of the Secretary of War with respect to navigable waters. It is not necessary to discuss the question of whether when the State of Illinois entered the Union in 1818 it joined with special reservations with respect to its own police powers. A reading of the Federal decisions from Gibbons vs. Ogden, 9 Wheat, 1, down to the present date leaves no escape from the thought that the States in adopting the Constitution surrendered to the central government everything, without stint or reservation, so far as the terms of the Constitution are concerned. The right to regulate commerce was conferred with many other things, and that right imposed upon the central government to see to it that navigation was not interfered with, either by individuals, the several States, or any foreign power. It is very true that it is the duty of the State of Illinois, in the exercise of its police power, to provide for the safety and welfare of its own people. On the other hand, if that

safety and welfare depends upon the operation of the things granted to the central government, the State of Illinois must look to Congress for eventual aid or relief.

[fol. 234] The evidence shows, and Judge Landis found and I find that the waters of Lake Michigan and other navigable waters of the Great Lakes have been reduced in level by the amount of water in excess of 4,167 cubic feet per second withdrawn from Lake Michigan by the defendant. From the standpoint of the practical mariner the testimony may not be satisfactory. It was given by engineers more or less highly technical, but thoroughly equipped in their profession. In fact no Lake captain testified that by reason of the lowering of the level of Lake Michigan was navigation interfered with. I have grave doubts whether any boat has been stranded or delayed by reason of the action of the Sanitary District.

On the other hand, the water levels have been reduced, and the Secretary of War, in whom is reposed the sole authority in matters of this kind, has determined that there was an interference with navigation, and a permit to the Sanitary District to continue in its present withdrawals was refused.

The jurisdiction of the Court has not and could not be challenged, and an injunction must issue against the defendant.

The record shows that the Sanitary District of Chicago has expended in its work some hundreds of millions of dollars; and the evidence shows rather conclusively that no other system of disposing of the sewerage in the great district covered would work so well as that devised by the Sanitary District. The City of Chicago, since the Drainage District began to operate, has practically doubled in population. The district served by the Sanitary District holds more people than over forty states in the Union. The rate of typhoid fever since the completion of the Drainage Canal has been reduced [fol. 235] from seventy-five per hundred thousand to a negligible number.

The testimony of Government engineers shows that it would take from ten to twenty-five years for the Drainage District to erect sewerage treatment and disposal works to handle the sewerage within the Drainage District, if the flow of water was reduced from 10,000 to 4,167 cubic feet per second.

This matter is a subject which needs the consideration of thinking people, not only in the State of Illinois, but in the whole United States. The Treaty with Canada entered into some years ago seemed to contemplate an acquiescence on the part of the Canadian Government to the withdrawal of 10,000 cubic feet a second by the Drainage District. However that may be, the Secretary of War has not given his official consent. Whether the increased withdrawal should or should not be made is properly a political and not a legal question, in the absence of consent by the Secretary of War. The Legislature of the State of Illinois, the various civic bodies, the Association of Commerce, and senators and representatives should see to it that at the earliest possible moment the situation here is brought to the attention of Congress, so that by appropriate legisla-

tion the health and welfare of this great community may be safeguarded. I have no doubt that when the maatter is properly presented it will be taken up by Congress and by the State Department, and some plan devised which will bring about adequate and the desired results.

It goes without saying that this Court will not issue an injunction to be effective forthwith. It cannot impose the conditions so [fols. 236 & 237] strenuously urged by the attorneys for the Sanitary District. It is doubtful whether the State of Illinois could authorize expenditures to be made in foreign states and foreign countries to restore the water levels.

On the testimony of the Government engineers the Court might, in the exercise of a sound discretion, delay the effectiveness of its injunction for from fifteen to twenty-five years to enable the Sanitary District or the State of Illinois to arrange for other means of disposing of the sewerage now handled by the Sanitary District.

Believing as I do that it is a matter for the immediate action of Congress, a decree may be prepared finding the facts as stated in the Bill and enjoining the defendant from withdrawing from Lake Michigan in excess of 4,167 cubic feet a second; the decree, however, not to go into effect for six months.

The matter must necesarily go to the Supreme Court of the United States for final settlement, and no doubt, if need be, when the record is there filed, application may be made to that Court for a supersedeas or further stay.

Carpenter, Dist. Judge. 18 June, 1923.

Carpenter, Judge. June 18th, A. D. 1923.

[fol. 242] IN THE DISTRICT COURT OF THE UNITED STATES FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

PETITION FOR APPEAL—Filed June 29, 1923

The Sanitary District of Chicago, defendant herein, respectfully shows:

Defendant is aggrieved by the judgment and decree herein rendered on June 18, 1923, in favor of the plaintiff and against the defendant, enjoining and restraining the defendant, its Board of Trustees, officers, agents, attorneys, representatives, employees and servants, and all persons acting or claiming or assuming to act under its authority, as prayed in the plaintiff's complaint, from diverting or abstracting water from Lake Michigan in excess of

250,000 cubic feet per minute; and the defendant, for the reasons specified in the assignment of errors filed herewith, desires to appeal from said decree to the Supreme Court of the United States, and desires that said appeal shall operate as a supersedeas and may suspend during the pendency of said appeal, the effect of said injunction.

Wherefore, defendant prays that the said appeal may be allowed and that the said appeal may operate as a supersedeas and may suspend during the pendency of said appeal the effect of said in-
[fols. 243–245] junction and decree; that said appeal be made returnable to the Supreme Court of the United States according to law, and that a transcript of the record, proceedings, papers and exhibits upon which said decree was rendered, duly authenticated, be sent to said Supreme Court of the United States, and defendant prays for all general and equitable relief.

Clyde L. Day, Edmund D. Adcock, Solicitors for Defendant.

[File endorsement omitted.]

[fol. 246] In the District Court of the United States, Northern District of Illinois, Eastern Division

[Title omitted]

Assignment of Errors—Filed June 29, 1923

Now comes the above named defendant, the Sanitary District of Chicago, and says that the final order or decree made and entered herein on the eighteenth day of June, 1923, granting the injunction prayed in the bill of complaint, is erroneous and against the just rights of said defendant, for the following reasons:

(1) Because, as appears from the record in this cause, the plaintiff was not entitled to the injunction granted in said order or decree enjoining the defendant, its Board of Trustees, officers, agents, attorneys, representatives, employes and servants, and all other persons acting or claiming or assuming to act under its authority, from diverting or abstracting any waters from Lake Michigan over and above or in excess of 250,000 cubic feet per minute, and the Court should have refused to enter any order or decree enjoining and restraining the defendant concerning or in respect to the subject matter of said complaint, and should have dismissed plaintiff's
[fol. 247] complaint for want of equity.

(2) Because under the Commerce Clause of the Constitution of the United States, Article I, Section 8, Clause Third, wherein Congress is given power to regulate commerce with foreign nations and among the several states and with the Indian tribes, neither Congress nor any officer of the United States has power or authority to regulate or limit the State of Illinois or the Sanitary District of

Chicago, a municipal corporation created under its authority, in abstracting or diverting water from Lake Michigan for public welfare and in exercise of the state's police power within the limits proposed by defendant, and as and in the manner abstracted or diverted or proposed to be abstracted or diverted.

(3) Because the diversion of water from Lake Michigan by defendant to the Desplaines and Illinois Rivers by means of a canal, called herein for convenience "Main Channel," and the reversal of the flow of the Chicago River and certain of its branches, including diversion works supplementary thereto, as appears by the record, has been, is being, and is proposed to be done in the exercise of the police powers of the State of Illinois for the benefit of public health and welfare.

(4) Because the diversion of water from Lake Michigan by defendant to the Desplaines and Illinois Rivers by means of its Main Channel and the reversal of the flow of the Chicago River and certain of its branches, including diversion works supplementary thereto, as appears by the record, has been, is being, and is proposed to be [fol. 248] done in the exercise of the police powers of the State of Illinois, and has been and is the only means by which the sewage of Chicago and its surrounding territory within the territorial limits of the Sanitary District of Chicago may be diverted from Lake Michigan, the only drinking water supply for the population of said area, to protect health and preserve lives.

(5) Because the diversion of water from Lake Michigan by defendant to the Desplaines and Illinois Rivers by means of its Main Channel and the reversal of the flow of the Chicago River and certain of its branches, including diversion works supplementary thereto, as appears by the record, has been, is being and is proposed to be done in the exercise of the police powers of the State of Illinois, and is necessary for the public health and welfare and to protect health and preserve lives.

(6) Because the diversion of water from Lake Michigan by defendant to the Desplaines and Illinois Rivers by means of its Main Channel and the reversal of the flow of the Chicago River and certain of its branches, including diversion works supplementary thereto, as appears by the record, has been, is being and is proposed to be done in the exercise of the police powers of the State of Illinois, and is necessary to prevent public nuisances and the breeding of diseases.

(7) Because the defendant, as appears by the record, in diverting water from Lake Michigan in excess of 250,000 cubic feet of water per minute, and in proposing to continue to do so, has been and proposes to continue so doing pursuant to and under an Act of the General Assembly of the State of Illinois passed May 29, 1889, and [fol. 249] in force July 1, 1889, which said Act expressly directs the defendant to divert and abstract through its diversion works water from Lake Michigan at the rate of 20,000 cubic feet of water per

minute for each one hundred thousand of the population of the defendant, such population being now approximately three million people, requiring a diversion of six hundred thousand cubic feet per minute, and said Act of the General Assembly of May 29, 1889, was passed in exercise of the police powers of the State for the public health and welfare, and the acts of the defendant taken thereunder have been, are, and are proposed to be for such purposes.

(8) Because said Act of May 29, 1889, of the General Assembly of Illinois, and Acts amendatory thereof and supplementary thereto, were passed for the sole and only purpose of preserving health and protecting life under the State's police power, and the operation of the defendant's diversion works has been and is for the same purpose, and neither Congress nor any officer of the United States can interfere under the Constitution of the United States with the reasonable exercise of such power.

(9) Because the operation and maintenance of defendant's diversion works under the authority of the State of Illinois for the public health and welfare, as appears by the record, cannot be interfered with by the United States, and particularly if the alleged interference with navigation or impairment thereof is only an indirect result of the operation of said works, the primary and sole purpose of the operation of said works being for the public health and welfare [fol. 250] of the people of the State. The power and authority under which said works have been built and are operated and maintained is a power reserved to the states and not delegated to the United States or Congress under the Constitution.

(10) Because as appears by the record a pure, wholesome, potable drinking water supply for the people of Chicago and its environs and for the people residing within the territorial limits of the Sanitary District of Chicago, cannot be obtained or provided except by the operation and maintenance of the diversion works of defendant and the abstraction from Lake Michigan of 20,000 cubic feet per minute for each hundred thousand of the population thereof, such population being now in excess of three million people requiring water diversion, much greater than 250,000 cubic feet per minute.

(11) Because as appears by the record no works can or may be constructed to take the place of the diversion works operated and maintained by the defendant whereby a pure, wholesome, potable drinking water supply may be provided for said population within the territorial limits of defendant, and whereby the abstraction or diversion of water from Lake Michigan may be reduced to 250,000 cubic feet per minute or to any amount approximately said volume of water.

(12) Because, as appears by the record, no works or means may be constructed or provided supplementary to or to be operated in conjunction with the diversion works built, operated and maintained by defendant whereby the diversion and abstraction of water from Lake Michigan may be reduced or limited to 250,000 cubic feet of

[fol. 251] water per minute or to any amount of water approximating said volume and whereby a wholesome drinking water supply may be provided for the people residing within the limits of the Sanitary District of Chicago.

(13) Because, as appears by the record, the reduction of or limitation of the abstraction and diversion of water from Lake Michigan to 250,000 cubic feet per minute by defendant or any amount approximating said volume as provided by said injunctional decree and within the time provided by said injunctional decree, would immediately cause a great public nuisance to exist in the Chicago River, the Desplaines and Illinois Rivers, and the waters of Lake Michigan at Chicago would become contaminated by sewage, breeding typhoid and other water-born diseases in the people whose only drinking water supply is obtained from Lake Michigan.

(14) Because, as appears from the record, works cannot be constructed to supplement the diversion works built, operated and maintained by defendant which will provide a reasonably pure drinking water supply for Chicago and whereby the abstraction and diversion of water from Lake Michigan may be reduced to 250,000 cubic feet of water per minute within any period less than twenty years.

(15) Because, as appears by the record, it will be necessary in order to supplement the diversion works of defendant with a diversion from Lake Michigan limited to 250,000 cubic feet of water per minute to construct what are known and called artificial sewage purification works, the cost of which is upwards of One Hundred Million Dollars ($100,000,000), and, further, the construction and [fol. 252] maintenance of works to filter the water supply of Chicago costing upwards of Sixty Million Dollars ($60,000,000), which works cannot be built, constructed and placed in operation within any period of less than twenty years.

(16) Because, as appears by the record, the total amount of money that may be devoted to construction work that defendant can raise from taxation and by the issuance of bonds within the limits of the Constitutional requirements of the State within the period of twenty years does not exceed One Hundred and Six Million Dollars ($106,000,000), and such amount can only be raised and provided by such means from time to time during said period, and the last portion of such amount can only be raised at substantially the end of said twenty year period.

(17) Because, as appears by the record, the diversion works constructed, maintained and operated by defendant were built, constructed and maintained to divert from Lake Michigan a total ultimate volume of 600,000 cubic feet of water per minute in order to keep the Chicago River and certain of its branches to its Main Channel flowing in a reverse direction from its original flow and away from Lake Michigan, so that none of the sewage emptied into said river by means of many sewers, could find its way to Lake Michigan

from the Chicago River when it is at flood stages which occurs many times during the year, and such flood stage run-off of the Chicago River drainage area is 600,000 cubic feet of water per minute; and also so that the sewage thus diverted into the Chicago River and to the Desplaines and Illinois Rivers will be diluted and free from nuisance or from danger of injury or impairment to [fol. 253] the public health and fish life in the Desplaines and Illinois Rivers.

(18) Because the Act of Congress of March 2, 1827, entitled "An Act to grant a quantity of land to the State of Illinois for the purpose of aiding in opening a canal to connect the waters of the Illinois River with those of Lake Michigan," granting among other things to the State certain land to aid the State in opening a canal to unite the waters of the Illinois River with those of Lake Michigan, authorized and empowered the State of Illinois directly or through any municipal agency to divert and abstract from Lake Michigan water to the extent of 600,000 cubic feet per minute as provided and proposed by defendant's works constructed, operated and maintained, and, as appears by the record, defendant in constructing and operating said works has been and is so acting under authority of the State expressly granted by Congress.

(19) Because, as appears by the record, the State immediately commenced to exercise the authority granted by said Act of Congress of March 2, 1827, and built a canal whereby water of Lake Michigan was diverted for the purpose of its operation; and thereafter enlarged said canal for navigation purposes, diverting a greater amount of water from Lake Michigan for such purposes; and thereafter in further exercise of said power and authority, created the defendant and caused it to build a canal of greater dimensions in depth and width than the original canal, to replace the old one called the Illinois and Michigan Canal, which new canal was designed to and does abstract water to the amount of 600,000 cubic feet per minute for navigation as well as sanitary purposes; and has replaced for all navigation pur- [fol. 254] poses the old Illinois-Michigan Canal between Joliet and Chicago, and has further united the waters of the Illinois River with those of Lake Michigan; and the said canal built and maintained by defendant as aforesaid is one of the navigable waters of the United States connecting various other navigable waters.

(20) Because the said Main Channel and defendant's other diversion works were built and are maintained and operated under the authority of the State of Illinois as expressly authorized by said Act of Congress of March 2, 1827.

(21) Because the State of Illinois by merely constructing the old Illinois-Michigan Canal did not exhaust its power and authority under said Act of March 2, 1827, but had the further power and authority under said Act to create the Sanitary District of Chicago and provide that it should build and construct said canal and diversion works to abstract and divert from Lake Michigan up to 600,000 cubic feet of water per minute, and in excess of 250,000

cubic feet per minute for navigation on said canal, Desplaines and Illinois Rivers, and for purposes of protecting the health and lives of part of the people of the State.

(22) Because, as appears by the record, the United States during the course of the enlargement of the old Illinois-Michigan Canal and the replacement thereof by the defendant as aforesaid through Congress and its executive officers not only acquiesced in the enlargement of said Illinois-Michigan Canal and the construction of the canal built and operated by the Sanitary District of Chicago requiring the diversion of water from Lake Michigan to the amount of 600,000 cubic feet per minute for navigation and sanitary purposes, [fol. 255] but also invited such enlargement of said Illinois-Michigan Canal and the construction and operation of said canal of the defendant to divert from Lake Michigan an amount of water ultimately equal to 600,000 cubic feet per minute.

(23) Because, as appears by the record, the Secretary of War and Congress through the Secretary of War transmitting annual report of the Chief of Engineers of the United States Army, had full and complete knowledge of the passage of the Act of the General Assembly of the State of Illinois of May 29, 1889, expressly providing for the construction of the Main Channel and diversion works of the defendant and the abstraction of water from Lake Michigan to the ultimate amount of 600,000 cubic feet per minute; and they also had knowledge by the same means of the commencement immediately thereafter of the construction of such works, the progress of the construction, and their completion on or about the year 1898, which said diversion works so provided to be constructed and constructed during said period could only be operated for the purposes intended, with a diversion and abstraction of water from Lake Michigan to the ultimate amount of 600,000 cubic feet per minute; and Congress has not only not legislated in any manner to interfere with the operation of said works of defendant but, on the contrary, has passed many Acts indicating its recognition of said diversion to the ultimate amount of water mentioned.

(24) Because, as appears by the record, Congress has by Acts passed fixed project depths for substantially all the harbors and [fol. 256] connecting waters of Lakes Superior, Michigan, Huron, Erie and Ontario since the completion and commencement of the operation of the defendant's diversion works and the diversion of water to the ultimate amount of 600,000 cubic feet per minute, and said project depths in said harbors and connecting waters have at all times existed and have always been the depths of waters in said harbors and connecting waters so provided by Congress, notwithstanding the claimed lowering of the elevations of the surface of Lakes Michigan, Huron, Erie and Ontario and their connecting waters by said abstraction to said ultimate amount of 600,000 cubic feet per minute.

(25) Because Congress under the Commerce Clause of the Constitution has power for the improvement of navigation to improve the

harbors, connecting channels and waters of the Great Lakes by deepening such channels and harbors or otherwise improving same and by fixing the depth of water that shall be provided in said harbors and channels through such improvement of nagivation; and, as appears by the record, in the exercise of such power Congress has so fixed said project depths; and, as it further appears by the record, at no time has the actual depth of water in such channels and harbors been less than the project depths so fixed by said Acts of Congress, and the diversion of water from Lake Michigan has not to the ultimate amount above mentioned impaired or lessened said depths or caused the depth of water to be less than the project depths so fixed by Congress.

(26) Because, as appears by the record, the cost and financial burden to defendant of building works which would approach the [fol. 257] proper protection of the water supply of the people within the territorial limits of the defendant, to take the place of the diversion in excess of 250,000 cubic feet per minute and up to 600,000 cubic feet per minute, would be, including increased cost of operation, upwards of $250,000,000., whereas the damage to plaintiff claimed by reason of the alleged injury to navigation by such diversion is slight.

(27) Because, as appears by the record, all the claimed damage to navigation by the diversion made and proposed by defendant can be offset or compensated for by the construction of works whose cost would not exceed $475,000.

(28) Because it is an uncontroverted fact, as appears by the record, that submerged weirs or dams may be constructed in the St. Clair and Niagara Rivers under the authority of the United States at a cost estimated by the United States Army Engineers to be not in excess of $475,000, which will have the effect of raising the surface elevations of the waters of Lake Michigan, Lake Huron and Lake Erie and their connecting waters to an amount equal to the alleged lowering of the surface elevations of said Lakes and their connecting waters by the diversion of water from Lake Michigan by defendant to the amount of 600,000 cubic feet per minute, and pursuant to the Rivers and Harbors Act of Congress of June 25, 1910, a report was made to Congress by the commission thereunder appointed, approved by the Secretary of War, recommending that such works be constructed, providing the State of Illinois or some agency of the State should provide the funds therefor, and as it further appears by the record the construction of the Gut dam in the Galops [fol. 258] rapids has already caused surface elevation of the water of Lake Ontario to be raised an amount equal to the claimed lowering due to defendant's diversion.

(29) Because, as appears by the record, the defendant in this case has offered, pursuant to ordinance of its Board of Trustees, to pay not only the cost of the construction, but also the maintenance of any works that may be provided by the authority of the United States to offset or compensate for alleged lowering of the surface

elevations of waters of the Great Lakes system due to the diversion of water from Lake Michigan to the amount of 600,000 cubic feet per minute.

(30) Because, as appears by the record, the defendant presented said offer by a motion and asked that the defendant be not enjoined from taking an amount of water less than 600,000 cubic feet per minute, on condition that the defendant be decreed to pay such cost, and the Court by order denied said motion.

(31) Because Congress by the Rivers and Harbors Act of March 3, 1899, March 2, 1907, and June 25, 1910, provided and appropriated for survey and estimate of costs of waterway from and connecting with the southern terminus of the Sanitary District's diversion canal replacing the Illinois-Michigan Canal along the Desplaines and Illinois Rivers, which said proposed waterway for which survey and estimate of cost was made under said Acts contemplated the use of water from Lake Michigan diverted by the Sanitary District to the amount of 600,000 cubic feet per minute.

(32) Because by Acts of Congress of March 3, 1909, June 25, 1910, August 24, 1912, and June 30, 1917, providing for the in-
[fol. 259] vestigation and report upon the best means of compensating for the lowering of the surface elevations of the Great Lakes and their connecting waters, due not only to the alleged diversion of water by the defendant to the amount of 600,000 cubic feet per minute, but also to diversions from other sources, Congress has expressly indicated its recognition of such diversions as existing lawful diversions and necessary to be continued, and Congress thereby proposes in connection therewith to take means by which the alleged or claimed injury to navigation may be taken care of without impairing the usefulness of said diversion works for the purposes for which they have been created and are being maintained.

(33) Because the Act of Congress of June 29, 1906, relating to the diversion of water from the Niagara River expressly states it shall not in any manner affect diversions for sanitary or domestic purposes, the diversion by defendant to 600,000 cubic feet per minute being the principal one for sanitary and domestic purposes, and said Act is in part as follows:

"That the diversion of water from Niagara River or its tributaries in the State of New York is hereby prohibited except with the consent of the Secretary of War as hereinafter authorized in Section 2 of this Act, provided that this prohibition shall not be interpreted as forbidding the diversion of the waters of the Great Lakes or of the Niagara River for sanitary or domestic purposes or for navigation, the amount of which may be fixed from time to time by the Congress of the United States or by the Secretary of War of the United States under its direction,"

and said Act expressly indicates that such diversions for sanitary or
[fol. 260] domestic purposes from the Great Lakes was not, and

should not be limited except by future Acts of Congress or by the Secretary of War under some future Act or Acts.

(34) Because the construction of the works of Sanitary District of Chicago to divert from Lake Michigan an ultimate amount of 600,000 cubic feet of water per minute was authorized by law of the State of Illinois and was, therefore, works expressly recognized as valid by Section 10 of the Rivers and Harbors Act of Congress of September 19, 1890, wherein it was provided only "that the creation of my obstruction not affirmatively authorized by law to the navigable capacity of any waters in respect of which the United States has jurisdiction is hereby prohibited," and Section 10 of the Rivers and Harbors Act of March 3, 1899, providing "that the creation of any obstruction not affirmatively authorized by Congress to the navigable capacity of any waters of the United States is hereby prohibited", was not intended to affect obstructions theretofore constructed or created pursuant to Acts of the General Assembly of the State of Illinois under the exercise of police power.

(35) Because the Acts of Congress passed contemporaneously with, during and after the construction of the diversion works of the defendant to the amount of 600,000 cubic feet of water per minute indicate that it was and is not the intention of Congress that the Rivers and Harbors Act of March 3, 1899, and particularly Sections 9, 10 and 12 thereof, should authorize or empower the Secretary of War or the Chief of Engineers to in any way prohibit, modify or control the diversion of water from Lake Michigan by defend- [fol. 261] ant through its various works to the ultimate amount of 600,000 cubic feet per minute.

(36) Because Sections 9 and 10 of the Rivers and Harbors Act of March 3, 1899, only authorize the Secretary of War acting in conjunction with the Chief of Engineers of the United States Army to grant or refuse a permit to build, construct or operate works affecting navigable waters of the United States.

(37) Because the Secretary of War under said Rivers and Harbors Act of March 3, 1899, Sections 9 and 10 thereof, is not authorized to control or in any manner supervise the operation of such works.

(38) Because, as appears by the record, on May 8, 1899, the Secretary of War acting in conjunction with the Chief of Engineers of the United States Army issued a permit to the defendant to open and operate its canal to divert water to the ultimate amount of 600,000 cubic feet per minute, and said permit was subject to the conditions that if Congress acted on the subject matter then the permit should be subject thereto, and also if at any time it should become apparent that the current in the Chicago River should be unreasonably obstructive to navigation then the Secretary of War might modify the amount of the diversion; and the Chicago River and its south branch and west fork was to and does furnish the connection between Lake Michigan and the northern terminus of defendant's

Main Channel extending from Chicago to Joliet, and thus the supply channel for the main channel of water from Lake Michigan, and said Chicago River and its south branch and west fork was [fol. 262] narrow, shallow and tortuous and thereby its flowage capacity was small; and by reason of the condition of the Chicago River and because of objections to the current therein as so expressly stated the Secretary of War attempted to modify or limit the diversion authorized under said permit of May 8, 1899, to 250,000 cubic feet per minute, which was done under a supposed permit dated May 5, 1901; and the defendant in view of such limitation of the amount of withdrawal and because of the shallowness and narrowness of the said Chicago River and its south branch and west fork thereof, made application to the Secretary of War for authority to increase the flowage capacity of the channel of said Chicago River and the south branch and west fork thereof by deepening it from its then depth of seventeen feet to the depth of twenty-six feet and widening at all points to two hundred feet for the purpose of providing an enlarged supply channel and the amount of water necessary for its Main Channel, so that the required amount of water to operate said diversion works taken through the Chicago River and the south branch and west fork thereof would not create a current in the channel of said rivers in excess of one and one-quarter mile per hour fixed by the Secretary of War; and said improvement of said Chicago River was made, as expressly stated in the application for permit therefor in order that the waters of Lake Michigan might be diverted to the amount of 600,000 cubic feet per minute, without creating a current in the Chicago River in excess of one and one-quarter miles per hour; and thereafter the defendant did improve the said Chicago River by deepening and widening it as above stated, at an expense of upwards of $13,000,000; and there has not been, is, and will not be, any [fol. 263] current in the Chicago River in excess of a mile and a quarter an hour by reason of abstraction of water from Lake Michigan in excess of 250,000 cubic feet per minute and to the ultimate amount of 600,000; and the so-called limitation of flow attempted to be made by the Secretary of War under said supposed permit of May 5, 1901, has ceased to have any force or effect, as the reason therefor has been removed.

(39) Because the Secretary of War and the Attorney General of the United States, in causing the institution of this suit and the filing of the complaint herein, and the prosecution of the said suit, have taken an unreasonable and arbitrary course and have thereby arbitrarily sought to enforce the provisions of the so-called permit of May 5, 1901, limiting the abstraction and withdrawal to 250,000 cubic feet of water per minute from Lake Michigan, when said limitation of flow was made solely because of the current in the Chicago River and the United States has not sought in this suit by its complaint to base its right to an injunction upon the conditions of navigation on the Chicago River but solely upon the condition of navigation on the Great Lakes, their connecting waters and harbors other than the Chicago River and its harbor.

(40) Because, as appears by the record, the Secretary of War has authorized the withdrawal of water from Lake Michigan to the amount of 600,000 cubic feet of water per minute and any limitation of withdrawal thereafter made under the conditions of the original permit of May 8, 1899, has ceased to have any force or effect, as [fol. 264] the express reason for such limitation of withdrawal has been removed by the defendant's constructing works and making improvements in the Chicago River and south branch and west fork thereof pursuant to the permit of the Secretary of War and for the purpose of removing the reason for such limitation of the amount of withdrawal.

(41) Because, as appears by the record, the abstraction and withdrawal of water from Lake Michigan to the amount of 600,000 cubic feet per minute has not and will not impair the navigable capacity of any of the navigable waters of the United States.

(42) Because, as appears by the record, the abstraction and withdrawal of water from Lake Michigan by the defendant to the amount of 600,000 cubic feet of water per minute has not and will not substantially impair or affect the navigable capacity of any of the navigable waters of the United States.

(43) Because, as appears by the record, no effect of such withdrawal or abstraction of water has been observed.

(44) Because, as appears by the record, no lay witness or navigator or captain of any ship or any one engaged in navigation upon the Great Lakes has testified as to any effect upon the navigable capacity of any of the harbors or connecting waters of the Great Lakes by the diversion of water by the defendant to the amount of 600,000 cubic feet per minute.

(45) Because, as appears by the record, the only basis upon which [fol. 265] plaintiff sought the injunctional decree or upon which the injunctional decree was or could be based was the testimony of expert witnesses and analyses made by them.

(46) Because, as appears by the record, the injunctional decree herein is only based upon the analyses of expert witnesses.

(47) Because, as it appears from the record, the evidence herein does not show that the surface elevations of the waters of the Great Lakes or their harbors, or connecting channels, or any of such waters, have been or will be lowered or affected in any manner by the diversion of water at Chicago.

(48) Because, as it appears from the record, the evidence herein does not show that the surface elevations of the waters of the Great Lakes or their harbors, or connecting channels, or any of such waters, have been materially or substantially lowered, or have been materially or substantially affected by the diversion of water at Chicago.

(49) Because, as appears by the record, the injury and damage to the defendant resulting from and by reason of the injunctional de-

cree entered herein will be financially great, whereas the benefit to the plaintiff resulting from and by reason of said decree will be slight.

(50) Because, as appears by the record, it will be impossible for [fol. 266] the defendant to provide adequate means to protect the water supply of the people of Chicago and within the territorial limits of the defendant with the diversion of water from Lake Michigan reduced to 250,000 cubic feet per minute, whereas the benefit to navigation upon the Great Lakes, their harbors and connecting waters, will be slight and scarcely appreciable.

(51) Because, as appears from the record, the defendant could not observe the injunction granted by said decree of June 18, 1923, without causing contamination of the drinking water supply of a population of upwards of 3,000,000 people within the territorial limits of the defendant, which contamination of drinking water supply would cause epidemics of typhoid fever and other water-borne diseases.

(52) Because, as appears from the record, the said injunctional decree entered herein in effect holds unconstitutional the Act of the General Assembly of the State of Illinois of May 29, 1889, wherein the defendant is directed to withdraw from Lake Michigan not less than 20,000 cubic feet of water per minute for each 100,000 of population within its territorial limits, which said act was passed under a power reserved to and in the State of Illinois under the Constitution.

(53) Because, as appears from the record, the Rivers and Harbors Act of June 13, 1902, Section 4 thereof, provided that the President of the United States might invite the Government of Great Britain to join in the formation of an International Commission to [fol. 267] be composed of three members from the United States and three who should represent the interests of the Dominion of Canada, whose duties should be to investigate and report on conditions and uses of the waters adjacent to the boundary line between the United States and Canada, upon the maintenance and regulation of suitable levels, the effect of diversions therefrom and the necessary measures to regulate such diversions; and, it was further provided, that the Commission should make recommendations as to the terms of a treaty concerning said boundary waters; and said Commission, known as International Waterways Commission, contemplated by said Act, was thereafter formed in the manner described; and the said Commission made special investigation of the diversion of water by the defendant, the amount thereof, the necessities for same, and recommended that the diversion of 600,000 cubic feet per minute by defendant should not be disturbed; and the said International Waterways Commission made an investigation of the uses of the waters of the Great Lakes, the priority of the different uses and what use should take precedence of all other uses, and found that the use of said waters for sanitary and domestic purposes should take precedence of all other uses, including use for navigation; and the said

International Waterways Commission also made reports and recommendations concerning the terms of the treaty with reference to boundary waters made January 11, 1909, and by said treaty it was provided that existing uses of water should not be disturbed; that use for domestic and sanitary purposes should take precedence of all other uses; that at Niagara Falls there might be diverted 36,000 cubic seconds feet of water on the Canadian side and on the American side 20,000 cubic seconds feet, and such difference was due principally [fol. 268] to the fact that the United States was charged with 10,000 cubic seconds feet, or 600,000 cubic minutes feet, diversion by defendant.

(54) Because, as appears from the record, the treaty between the United States and Great Britain of January 11, 1909, relating to and concerning the boundary waters between the United States and Canada expressly recognizes and authorizes the diversion by the defendant to the amount of 600,000 cubic feet per minute from Lake Michigan and the Great Lakes System.

(55) Because, as appears from the record, the treaty of January 11, 1909, precludes the plaintiff's obtaining an injunction with reference to withdrawal of water from Lake Michigan by defendant as to any amount less than 600,000 cubic feet per minute.

(56) Because the Court should have granted and allowed the motion presented on July 12, 1920, containing the offer of defendant to defray the cost of constructing and maintaining any compensating works the United States might determine to build to offset for the alleged lowering of the surfaces of the Great Lakes and their connecting channels and harbors, and should have entered a decree only enjoining the defendant from diverting water from Lake Michigan in excess of 600,000 cubic feet per minute on condition that such cost of constructing and maintaining said works should be paid when demanded by the plaintiff.

(57) Because it does not appear from the record that the diversion of water from Lake Michigan to the amount of 600,000 cubic feet per minute is under all the facts and circumstances an unreasonable obstruction to navigation.

[fol. 269] (58) Because, as appears from the record, the decree herein in effect permits the Secretary of War and the Attorney General to pursue an unreasonable and arbitrary course with reference to the defendant's diversion of water from Lake Michigan.

(59) Because, as appears from the record, the Court should have balanced the equities and entered a decree which would do complete justice between the parties, and should have refused to enter the injunctional decree herein causing unreasonable damage and injury to the defendant.

(60) Because, as appears from the record, the plaintiff did not show that the abstraction of water from Lake Michigan by the de-

fendant to the amount of 600,000 cubic feet per minute under all the circumstances would amount to an unreasonable obstruction to navigation, having consideration for not only the effect upon navigation but also the purpose of the withdrawal—the public benefit inuring to the people as compared to injury to or interference with navigation.

(61) Because Congress will not be deemed to have acted concerning a matter of local regulation such as is embraced in the Act of the General Assembly of Illinois of May 29, 1889, providing for the construction and operation of defendant's diversion works unless it has passed a special law with reference to the particular alleged obstruction or regulation.

[fol. 270] (62) Because, as appears from the record, the plaintiff is estopped or is in no position to assert that the works of the defendant were erected and were operated, and are being operated, without authority or constitute a nuisance; and when the United States comes in to a court of equity it stands in no different position than any other plaintiff in equity.

Wherefore, the defendant, the Sanitary District of Chicago, prays that said decree of the District Court of the United States, for the Northern District of Illinois, Eastern Division, be reversed, and that the said District Court of the United States, for the Northern District of Illinois, Eastern Division, may be directed to enter a decree dissolving and vacating the injunction granted by it on said June 18, 1923.

The Sanitary District of Chicago, by Clyde L. Day, Edmund D. Adcock, Its Solicitors.

[Title omitted]

ORDER ALLOWING APPEAL

Considering the petition for appeal of the defendant, the Sanitary District of Chicago, this day presented.

It is ordered that an appeal be allowed to said defendant herein from the decree of June 18, 1923, rendered against said defendant in the above entitled and numbered cause, and that said appeal shall be returnable to the Supreme Court of the United States, and that, upon the execution, filing and approval of a bond in the penal sum of Five Thousand Dollars ($5,000), said appeal shall operate as a

supersedeas of said decree and shall suspend during the pendency of said appeal, the effect and operation of the injunction herein.

Enter.

Carpenter, Judge. 29th June, 1923.

[fol. 275] IN THE DISTRICT COURT OF THE UNITED STATES FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

ORDER RE TRANSCRIPT OF EVIDENCE

This cause came on at this term and was argued by counsel, and thereupon, upon consideration thereof, it was ordered, adjudged and decreed, as follows:

(1) The evidence taken in this cause in the exact words of the witnesses as it appears in certain printed bound volumes numbered 1 to 7, including also typewritten transcript of evidence taken on, towit, April 25th and 26th, 1923, together with exhibits, is practically impossible to put into narrative form which will disclose the vital merits of the cause. Said evidence is in printed form and consists principally of statements and evidence of expert witnesses whose testimony appearing in the record cannot be materially condensed, and of documentary evidence, which in the form they now appear in the record, are sufficiently condensed.

(2) The said evidence shall be set out in the exact words of the witnesses as it appears in the said printed documents and in the said typewritten testimony taken on April 25th and 26th, 1923, and the said seven printed volumes which are identified by the signature of the Clerk of the Court on the title page of each of said volumes numbered from 1 to 7, inclusive, and entitled on the back thereof "United States of America vs. Sanitary District of Chicago—Record," including said typewritten transcript taken April 25th and 26th, 1923, identified by the Clerk's signature, shall be incorporated [fol. 276] in the transcript of record on the appeal of said cause.

Enter.

Carpenter, Judge. 29th June, 1923.

[fols. 278–281] BOND ON APPEAL FOR $5,000—Approved to Operate as a Supersedeas and Filed June 29, 1923

[fol. 282] IN THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

ORDER RE TRANSCRIPT OF EVIDENCE

This cause came on to be further heard at this term and was argued by counsel, and thereupon, upon consideration thereof, it was ordered, adjudged and decreed, as follows:

(1) The testimony of all witnesses herein and various documentary evidence and exhibits was taken, offered or introduced, and the objections and exceptions to said evidence or testimony were made before Samuel M. Morgan, heretofore appointed as Commissioner to take and transcribe said testimony and evidence, and a transcript of all of said testimony and evidence before said Commissioner has been filed by him in this Court and certain other documentary evidence, offered, introduced or presented has been filed herein pursuant to stipulation of counsel, and all of said testimony and evidence offered, introduced or presented in the manner aforesaid, prior to February 15, 1915, has been printed and consists of seven printed volumes, including exhibits, which said seven volumes, including exhibits, is a correct and true copy as is agreed [fol. 283] by counsel for both parties of all of said testimony, evidence or exhibits offered, introduced and filed prior to said February 15, 1915, which said volumes are now here in open court and for identification bear the signature on the initial page of each volume of the clerk of this Court.

(2) The said printed volumes above described and identified as aforesaid, shall be treated and accepted in all respects the same as the original documents or depositions taken and filed prior to said February 15, 1915, and said printed volumes shall be substituted for said typewritten transcript of said testimony and evidence and stipulations as to facts, and shall be the record thereof, and said printed volumes so identified shall be filed by the Clerk of this Court for the purposes aforesaid.

ORDER EXTENDING TIME

The parties in the above entitled cause appearing here in open court by their respective solicitors, and for satisfactory reasons appearing to the Court, the time for filing the record in this cause in the Supreme Court of the United States pursuant to the appeal sued out is hereby extended until and including the 20th day of September, A. D. 1923.

Consolidated Cause No. 114.

UNITED STATES OF AMERICA

vs.

SANITARY DISTRICT OF CHICAGO

STIPULATION AS TO INCORPORATING ORIGINAL CERTIFICATE OF EVIDENCE IN THE TRANSCRIPT OF RECORD IN PLACE OF A COPY THEREOF—Filed June 29, 1923

It is hereby stipulated and agreed, by and between the parties hereto, represented by their respective solicitors, that the original certificate of evidence filed herein may be incorporated as a part of the transcript of record to be filed with the Clerk of the United States Supreme Court pursuant to the appeal herein, in place of a copy of said certificate of evidence.

Edwin A. Olson, United States Attorney; Joseph B. Fleming, Special Assistant Attorney General, Solicitors for Plaintiff.
Clyde L. Day, Edmund D. Adcock, Solicitors for Defendant.

[Title omitted]

Certificate of Evidence—Filed June 29, 1923

Be it remembered and certified, that on the hearing of this cause, the same being originally cause number 29019 and equity number 114, upon the said respective bills of complaint and answers, the following evidence was introduced by the parties hereto, to wit—the evidence as contained in the printed and bound volumes numbered 1 to 7, respectively, marked on the back thereof "United States of America vs. Sanitary District—Record," further identified by the signature of the Clerk of the Court on the title page of each of said seven volumes, and including typewritten testimony taken before the Commissioner on April 25th and 26th, 1923, entitled "United States of America vs. Sanitary District of Chicago," also further identified by the signature of the Clerk of this Court on the first page of said testimony, and said printed volumes identified as aforesaid including the said typewritten volume, are made a part hereof, the same as if attached hereto.

The following is a copy of the stenographic transcript of the opinion of Judge Landis delivered orally on June 19, 1920:

[fol. 292] OPINION OF JUDGE LANDIS IN SANITARY DISTRICT CASES

June 19, 1920.

I have sent for you gentlemen to dispose of the Sanitary District cases. Before taking up these cases, just a word about time and delay. Six years was spent after these cases were filed in taking testimony, and about six years has passed since the cases were submitted to me on briefs. The six years that was taken up while taking testimony was all necessary. The delay that has occurred since the matters have been submittetd to me have been the result of the exercise of my judgment. First, that during the war period, in view of the international questions possible, I thought it was better that this matter should continue just as it was, and secondly, since the war I have deferred entering this order with the understanding that there was a possibility of a composition of differences here that would enable the questions to be permanently adjusted along lines which I have been told were suggested by the Sanitary District to the War Department and the Canadian Government. I have held the matter, however, as long as I think proper on that theory and shall enter an order.

The bills were filed under legislation authorizing the United States to receive the injunctive power of the court as against obstruction of navigable waters and impairment of the navigable capacity of navigable waters. The averments, so far as I need to deal with the averments here now, are that the Sanitary District proposes to take an

amount of water—is taking an amount of water—proposing to take more, the taking of which will result in such impairment and such obstruction. Specifically, the impairment complained of most im- [fol. 293] portant in my view, is the impairment of the navigable capacity of the Great Lakes, excepting Lake Superior. The theory of the bills is—the charge is that such impairment by the district as is charged in the bills, without the consent of the Federal authorities at Washington, which consent is authorized and provided for by the Federal legislation, as I said before, entitles the government to an injunction. The defense of the Sanitary District is, first, that there is no impairment and no obstruction, and primarily, secondly, if there is an impairment or an obstruction, that it is necessary for the sanitation of this great populative territory. An examination of the proofs on the question of whether there is an impairment or not, an obstruction or not, that is to say, whether the taking of this water is felt or not, leads me to the conclusion that there is a lowering of the surface of this lake. In making that statement I have in mind the variation of the lake levels, traditional variation of the lake levels, known to all men that know anything about it. All that time finding that there is a lowering of the lake level, yes. That the taking of this vast volume of water each minute of each hour of each day of each month of each year continued unceasingly, no evidence in this case discrediting the fact, and has entirely resulted in the lowering of the level of the lake, and has resulted in changing the current of the Chicago River and reversing the current of the Chicago River. Now that the variation is only a matter of inches in the level of Lake Michigan, it is without doubt in my judgment, on the evidence in the matter, a matter of inches, and being a matter of inches, even though it be no more than three or four, having in mind the state of proof as to the depth of the harbors in the Great Lakes, [fol. 294] it is directly an impairment of navigable capacity, and by leaving the bottom of the harbors that much closer, the water is the creation of an obstruction to the navigable waters of the United States; in other words, the question of fact—whether there is an impairment or obstruction here, are beyond controversy and beyond question, but the fact is clearly established that there is such a change in this lake level, in my judgment, so that in low lake level time the level is lower and in high lake level time it is less than it would be but for this diversion.

Q. How many cubic feet per minute now?

A. Just at present I think about 8,500 per second. 480,000 cubic feet per minute, that is approximately. The diversion is 480,000 cubic feet per minute. The finding of the court is, on the evidence in this case, that that has resulted in the lowering of the lake level and the reversal of these currents, which latter fact is not controverted, and on the evidence in the case that the lowering is an impairment, as I said before, an impairment of navigable capacity, even though it amounts to no more than three or four inches, and as to the lowering to that extent there could be no controversy on the record, so on that fact the court's finding is against the contention

of the defendant on the proposition that this is a necessary thing for the salvation of this community, that is, without this water this community will be at the mercy of diseases and germs from which it suffered before this diversion began and from which it has by this diversion been practically relieved of, as shown by statistics. The court has complied with the rule of law, that navigable rights are [fol. 295] paramount, and even though the district is driven to the necessity of making some other provision, granting that the War Department and Congress should refuse to give that contention to this question of sanitation, it is entitled to the law which is in force in this room on me, which I must obey, that a navigable right is paramount, and that in the last analysis should Congress and the War Department in consideration of all these matters decline to permit the necessary diversion, the burden is on the District of providing some other method of relief; in other words, the defense that is necessary for the purposes of sanitation as against the rule that a navigable right and navigation right is a paramount right, is immaterial.

I had hoped, as I stated at the beginning, that there might be a composition of this thing. The Judge has no right to have personal feelings, but I live in this community, and it was my hope that there could be devised a program that would enable this district to have the benefit of this water, as much as it needs, that will give to the country this water in the solving of this problem of navigation.

There will be an order striking or sustaining the exceptions of the plaintiff, certain paragraphs of your answer setting up this sanitation defense. There will also be another sustaining the operation of this order which I am entering here this morning until 30 days after the Sanitary District has an opportunity to present to the Supreme Court of the United States an application for a supersedeas against high water, that is 30 days after the date fixed for the meeting of the Supreme Court in October. The order will not go into effect, it [fol. 296] will be suspended until 30 days after the Supreme Court meets in October. That is plenty of time, is it not? A. Yes, sir. I think that is plenty of time. I have considered that is enough. I wanted to make no mistake. You can form it in a way so that you will have a final order to appeal from. You have got to have that in mind. You may draw an order effective 30 days after the Spureme Court meets.

I omitted to mention one matter here which is not important, except the control of the Federal Government over this question has been recognized from the beginning by the Sanitary District itself before the diversion began and continuously down until what was that year when they attached that order, 1909? A. I think 1907 or 1908.

From the beginning, prior to the beginning of the diversion and down to 1907 or 1908, the constant attitude of the Sanitary District was a recognition of the control of the Federal Government over this whole question, everything that was done by the Sanitary Dis-

trict in the way of diversion being in a permit granted by the War Department on application of the Sanitary District to that end. The Sanitary District shall have an opportunity to apply for further relief to the War Department at Washington. Under no circumstances does this order go into effect now. Make that 60 days, and you may put in it, if it does not destroy the appealability of the order, you may put in a provision retaining me in control. The thing that the Government wants, at least the court wants, being a citizen of Chicago, the thing I want is water without microbes. That is why I have held your lawsuit.

[fol. 297] The following is motion presented on July 12, 1920, and filed herein:

[fol. 298] IN THE DISTRICT COURT OF THE UNITED STATES FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

C. C. No. 29019 and Equity No. 114

UNITED STATES OF AMERICA, Complainant,

vs.

THE SANITARY DISTRICT OF CHICAGO, Defendant.

MOTION FOR RECONSIDERATION OF ORAL OPINION AND ORAL DIRECTION OF THE COURT CONCERNING THE FORM OF DECREE IN SAID TWO CAUSES, TOGETHER WITH GROUNDS OF SAID MOTION

C. Arch Williams, Attorney for Defendant. Edmund D. Adcock, of Counsel.

[fol. 299] [Title omitted]

Now comes The Sanitary District of Chicago, defendant, in said two causes, by C. Arch Williams and Edmund D. Adcock, its attorneys, and moves the court that it reconsider its oral opinion and oral direction heretofore announced concerning the form of decree to be entered in the said causes, and that the court direct that The Sanitary District of Chicago, defendant, be enjoined, only, from withdrawing or diverting from Lake Michigan, through its various works now constructed or under construction, more than ten thousand cubic feet of water per second from Lake Michigan on condition that if the Congress of the United States, or other competent [fol. 300] governmental authority, provides for the construction of, in the St. Clair, Niagara or St. Lawrence rivers, or in one or all of them, works to compensate for any diminishing levels of the Great Lakes and connecting waters, due to the diversion or with-

drawal of ten thousand cubic feet of water per second from Lake Michigan by The Sanitary District of Chicago, then The Sanitary District of Chicago shall defray the expense and pay the cost of the construction and maintenance of any such works upon request therefor by the United States of America. In connection with said motion, and as a part thereof, the defendant hereby offers and agrees to defray the expense or pay to the United States upon demand the cost of the construction and maintenance of the works of the character above described in accordance with an ordinance of the Board of Trustees of The Sanitary District of Chicago passed and approved by said Board on the 8th day of July, A. D. 1920, a copy of which said ordinance is hereto attached and marked Exhibit "A," a certified copy of which is here ready to be produced in court. In support of said motion, and as grounds therefor, the defendant alleges and shows the following:

(1) The first of said suits was instituted in the Circuit Court of the United States for the Northern District of Illinois, Eastern Division, in the year 1908 and particularly seeks to enjoin the construction and operation of the Calumet Sag Channel, then and now under construction, through which channel it was and is proposed to divert approximately two thousand cubic feet of water per second from Lake Michigan into the main channel of said district at Sag, [fol. 301] Illinois. The second of said suits was instituted in the District Court of the United States, for the Northern District of Illinois, Eastern Division, on October 6, 1913, by bill of complaint filed on said date wherein it was prayed that The Sanitary District be enjoined and restrained

"from diverting or abstracting any waters from Lake Michigan over and above and in excess of two hundred and fifty thousand cubic feet of water per minute, as already authorized by said Secretary of War * * *."

The said suit instituted in the said District Court therefore sought to enjoin the abstraction of waters by the District, not only through the main channel, but also through or by means of any other works then constructed, under construction, or to be constructed. The latter suit, therefore, embraces and covers the subject matter of the first suit. It was agreed by stipulation that any evidence introduced in any one of the said suits that would be material in the other might be used by either party.

(2) The ground upon which the complainant sought injunction, as shown by the evidence and the allegations of said bill of complaint, was that the diversion of water in excess of two hundred and fifty thousand cubic feet per minute, or four thousand one hundred sixty-seven cubic feet per second, would lower the levels of the Great Lakes and connecting waters, thereby injuring navigation and changing the navigable capacity of the navigable waters of the United States.

(3) It is an admitted and undisputed fact on the record in said causes that works may be installed in the St. Clair, Niagara and St. Lawrence rivers which will compensate for the lowering of the lake [fol. 302] levels due to a diversion at Chicago of ten thousand cubic feet of water per second. Witnesses for both the United States and The Sanitary District in said causes so testified. There was introduced in evidence in said cause a document entitled "Final Report Waterway from Lockport, Illinois, to the Mouth of the Illinois River, H. R. Document No. 762, Sixty-third Congress, Second Session." The said report was made pursuant to the River and Harbor Act of Congress of June 25, 1910, which provided:

"The Secretary of War shall appoint a board of five members, to be composed of four engineer officers of the army and one civil engineer, taken from civil life. * * * Said Board shall report upon * * * such measures as may be required to properly preserve the levels of the Great Lakes and to compensate, as far as practicable for the diminishing level in said lakes and the connecting waters thereof by reason of any diversion of water from Lake Michigan for the maintenance of the proposed waterway herein described, or diversion for any other purpose."

The Board of Engineers, provided for by said Act of Congress, so appointed, made an investigation and its report was submitted to the Board of Engineers for Rivers and Harbors on August 15, 1913. The Board of Engineers for Rivers and Harbors report, reviewing the report of the special board, is dated December 16, 1913. It is signed by General William M. Black, then senior member of the Board, who was later and for a number of years Chief of Engineers of the United States army. Concerning the Chicago diversion, the Board of Engineers for Rivers and Harbors, in its report stated:

"Further, the Board believes that the total volume of water to be [fol. 303] diverted from the natural discharge channels of the lakes should be definitely fixed by Congress; that a project with estimate of cost for works necessary to compensate for such diversion should be prepared to the satisfaction of the Chief of Engineers, and the Secretary of War; that before any diversion is made beyond that at present existing, the State of Illinois shall transfer to the Secretary of War the funds necessary for such works as given by approved estimate of cost that the work shall be built by the United States with the funds so provided and that the control and maintenance of such works shall be in and at the cost of the United States."

The Special Board's report upon the subject of compensating for diminished or diminishing lake levels is as follows:

"To restore the diminished levels in the lakes by constructing contracting works in their outlets does not however present any serious difficulties. A careful discussion of the proper locations and dimensions of such works is also given in Appendix A.

At the foot of Lake Ontario the closure of the Gut channel of the Galops Rapids by the Canadian Government has had the effect

of raising the level of Lake Ontario an amount nearly equal to the computed lowering of the lake by a diversion of 10,000 second feet at Chicago, and no compensation is at present deemed necessary to restore former conditions in this lake.

In Appendix A it is proposed to diminish the outflow of Lake Erie by the construction of three submerged weirs in Niagara River in the vicinity of Squaw Island, which would average about 4.2 feet in height and would contain about 15,000 cubic yards of masonry. The estimated cost is $150,000.

To raise the level of Lakes Michigan and Huron submerged weirs [fol. 304] are proposed in St. Clair River, covering 3 miles of river below the mouth of Black River at Port Huron. The weirs as suggested in Appendix A have a height of from 5 to 6 feet above the river bed, contain about 65,000 cubic yards of material, and their estimated cost is $325,000. It is computed that these weirs will increase the velocity of the water flowing over them slightly (from a mean of 3.28 feet to 3.89 feet per second), but, on the other hand, above the mouth of Black River the river slopes and velocities which are now excessive will be diminished, and navigation on the whole will be considerably benefited.

The Chicago diversion has no effect on Lake Superior.

Compensation for the loss of elevation on Lakes Michigan, Huron and Erie, and their connecting waters, due to an assumed diversion from Lake Michigan of 10,000 second feet, will by the plan above outlined involve an expenditure of about $475,000, to which should be added an amount for the maintenance of the weirs, estimated at about $15,000 per year, the total cost being much less than the cost of restoration of depths by dredging. It is the opinion of the board that while other plans have been proposed compensation by fixed contraction works similar in general to those above described affords the cheapest and most satisfactory method of preserving the levels of the Great Lakes."

Said report is signed by W. H. Bixby, Brigadier General, U. S. Army, retired, President of the Board; C. McD. Townsend, Colonel, Corps of Engineers, U. S. Army; C. Keller, Major, Corps of Engineers, U. S. Army; J. B. Cavanaugh, Major, Corps of Engineers, U. S. Army; and John Bogart, Civil Engineer.

The Appendix A to said report is signed by C. Keller, Major, Corps [fol. 305] of Engineers, and is dated August 13, 1913. Concerning construction and effect of compensating works, Col. Keller states in his report as follows:

"The loss of depth on Lake Ontario, due to a diversion of 10,000 second-feet, would be 0.431 foot, or 5.2 inches. The closure of the Gut Channel of the Galops Rapids by the Canadian Government in 1903 has had the effect of raising the level of Lake Ontario by about the same amount. No further compensation is therefore at present necessary on Lake Ontario to restore its natural levels. The head of Galops Rapids will probably afford an advantageous site for a submerged dam or weir to obstract further the area of the channel through which Lake Ontario discharges, and no great

engineering difficulty should be experienced in securing any reasonable increase of level on this lake, but storage in this lake would, temporarily at least, diminish depths in the St. Lawrence River. * * *

For the channels and lakes from the foot of Lake Erie to the St. Marys Locks, so far as affected by the Chicago diversion, a plan of compensation seems feasible which will not disturb natural conditions.

To compensate for the reduction of level in Lake Erie, the outflow capacity of the Niagara River must be diminished. By building submerged weirs or contraction works a short distance below its head, this may be done without altering the range and the periods of the natural oscillations of the lake. At the same time, the free flow down the Niagara River will remain practically unchanged. A proper location of the weirs, which will be of moderate height, or of the contracting dikes will not increase the danger of ice gorges in the upper Niagara River. * * *

It is known that when the surface of Lake Erie is elevated there [fol. 306] will be some backwater effect on Lakes Michigan and Huron, estimated to be slightly more than one-third the rise of Lake Erie. Assuming the surface of Lake Erie raised 0.45 foot, it is estimated that the backwater rise of Lakes Michigan and Huron may be as much as 0.16. A diversion of 10,000 second-feet at Chicago would lower Lakes Michigan and Huron 0.47 foot, and the difference between this and the above backwater effect, or 0.31 foot, represents the additional amount which the surface of Lakes Michigan and Huron must be raised to compensate for such diversion. The St. Clair River is a main artery of the highly important lake traffic, and if submerged weirs are to be built in this river to raise the level of Lakes Michigan and Huron, sites must be chosen and the weirs built to such height that the depth over them will be ample and that navigation may remain convenient and unobstructed. The average depth of the St. Clair River for a considerable distance below the mouth of Black River at Port Huron is 30 feet, and six weirs may be built below that point, at distances averaging half a mile apart, which will raise the surface of Lakes Michigan and Huron the desired amount and will not reduce the depth over the weirs and elsewhere below 24 to 25 feet. The mean velocity of the current in this vicinity would be increased from about 3.28 feet to about 3.89 feet per second, or to about 2 2/3 miles per hour, and the effect of this increase would be felt over a distance of about 3 miles below the upper weir, while above it the river slopes and velocities, now excessive, will be diminished and navigation will be benefited. The weirs, located as above, should have a height of about 5 to 6 feet above the river bed, and six weirs would require about 65,000 cubic yards of stone, which, at $5 per cubic yard, will cost about $325,000. Contraction works in the same locality will, at higher cost, produce the same result, but they must, as previously noted, be restricted in height to mean stage.

[fol. 307] The Chicago diversion, nor any from the lower lakes, will have no effect upon Lake Superior.

The plan of compensation herein proposed has the advantage of simplicity and relative economy. Moreover, the submerged weirs may be systematically and progressively built, so as to permit close observation of their effect and such changes in plan as experience gained during construction may suggest. On the other hand, the Niagara River weirs, so long as they exist, would certainly interfere with the navigation of the main channel of the Niagara River, and at some future time might thereby interfere with the deepening of the channel. Present navigation would, however, be sufficiently served by the new lock at Black Rock. A further minor criticism of the proposed Niagara River weirs is that they do not, as would a high weir close to Niagara Falls, prevent the power diversions at Niagara from slightly lowering the level of Lake Erie; but the weirs are designed to compensate for the effects of diversions from Lake Michigan only. The consideration of compensation for the effects of diversions from the Niagara River is not included in the board's duties, but such compensation could readily be provided by slight modification of the weirs proposed.

Compensation for the loss of elevation on Lakes Michigan, Huron and Erie and connecting waters, due to an assumed diversion from Lake Michigan of 10,000 second-feet will, by the plan above outlined, involve a total expenditure of at least $475,000, to which must be added a small amount, possibly $15,000, annually, for the maintenance of the remedial works. This volume of 10,000 cubic feet per second has been assumed merely as a basis for computation. The cost of compensation for a diversion of different volume may be determined in the same manner."

[fol. 308] 4. On June 30, 1917, the Congress of the United States by joint resolution authorized and directed the Secretary of War to

"Make a comprehensive and thorough investigation, including all necessary surveys and maps, of the entire subject of water diversion from the Great Lakes and Niagara River, including navigation, sanitary and power purposes, and the preservation of the scenic beauty of Niagara Falls and the rapids of Niagara River, and to report to Congress thereon at the earliest practicable date."

Accordingly, the Chief of Engineers, by direction of the Secretary of War, authorized the Division Engineer, Lakes Division (Col. J. G. Warren, Corps of Engineers, U. S. Army), to make and prepare a report upon all the diversions of the Great Lakes. This report was recently submitted to the Board of Engineers on Rivers and Harbors, and, on June 3, 1920, the said Board had a hearing concerning the subject matter of said report at Niagara Falls, New York. At said hearing, representatives of persons, firms and corporations diverting water from the Great Lakes were present, including representatives of the various power companies and interests using the water of the Niagara River at or near Niagara Falls to develop for sale, for commercial purposes, electricity. Representatives of The Sanitary District of Chicago were present as were those of organizations desiring

to protect the scenic beauty of Niagara Falls. The said report has not yet been printed and is in typewritten form, and it is understood there are only two copies in existence—one is located at the office [fol. 309] of the Division Engineer at Buffalo and another at the office of the Board of Engineers for Rivers and Harbors, at Washington, D. C. The report, however, has been examined by representatives of The Sanitary District and the substance of same, with reference to the Chicago diversion and compensation therefor, can be stated, and the defendant asks the opportunity, at such time as the court may direct, to offer said report, or portions thereof, in evidence. The said report found that there were many diversions of the waters of the Great Lakes which effected the lowering of lake levels, and particularly the level of Lake Erie—such as the diversions at Niagara for power purposes, the diversion of 4,500 cubic-seconds feet for power purposes through the Welland Canal and other diversions, including the Chicago diversion; that the Chicago diversion of 10,000 cubic feet per second would produce approximately 55 per cent of the entire lowering of Lake Erie. The report further finds that any diminished or diminishing levels of the lakes due to the Chicago diversion, or any other diversion, may be compensated for by the construction of works in the St. Clair and Niagara rivers of the character described in said report entitled "Final Report, Waterway from Lockport, Ill., to the Mouth of the Illinois River," or by the construction and operation of so-called "regulating works" in the Niagara River, which said works would consist of dams which may be moved at will to regulate the levels of Lake Erie. It was recommended that The Sanitary District be allowed and permitted to withdraw from Lake Michigan 10,000 cubic second-feet of water and that works to [fol. 310] compensate for any diminished or diminishing lake levels should be built at the expense of The Sanitary District.

5. The treaty between the United States and Great Britain of 1909, relating to Canadian boundary waters, provided that there may be diverted from the Niagara River above Niagara Falls, on the Canadian side, water to the extent of 36,000 cubic feet per second and on the American side 20,000 cubic feet of water per second. The reason that the United States was only permitted to divert 20,000 cubic second-feet as compared with the Canadian right of 36,000 second-feet was because the United States was charged with the diversion of 10,000 second-feet at Chicago. Canada, therefore, can make no objection. The International Waterways Commission was organized and appointed pursuant to the joint action of the Congress of the United States and the Parliament of Canada. Canada and the United States each appointed three members thereof. The purpose of the orgnization of the International Waterways Commission was, among other things, to recommend the form of a treaty between the United States and Great Britain concerning the Canadian boundary waters. On April 25, 1906, the Canadian section of the International Waterways Commission made a report to the Commissioner of Public Works of Canada, as follows (proceedings I. W. C., page 333):

"At Chicago the Americans had built a drainage canal which, when in full operation will use about 10,000 cubic feet of water per second.

The quantity of water required for the purposes of a ship canal is comparatively small, but the character of this drainage canal at [fol. 311] Chicago is such as to involve the continuous flow of water, which will have the effect of lowering Lake Michigan, by over 6 inches and Lake Erie by 4½ inches. The nature of this work may be judged when we state that the expenditure will be over $40,000,000 and that power works are in the course of construction on the canal which will generate some 30,000 H. P.

As the diversion from Lake Michigan to the Mississippi River is of a much more serious character than the temporary diversions from the Niagara River, it is felt that the amount of water taken on the American side of the Niagara River should be limited to 18,500 cubic feet per second. * * * It is exceedingly important in the interest of navigation, both to ourselves and the people of the United States, that the diversion by way of the Chicago drainage canal should be limited. * * * If our proposal is carried out, the diversions will be about as follows:

Diversions on the American Side

	Per second cubic feet
Niagara Falls	18,500
Chicago Drainage Canal	10,000
Total	28,500

Diversions on the Canadian Side

Niagara Falls and on the Niagara Peninsula	36,000

It is quite apparent that no further diversion can be made on the Niagara River without injury to the scenic effect of the Falls as a whole, and there should be no further diversion from Lake Erie or any other of the waters of the Great Lakes system, which will be [fol. 312] injurious to navigation. Your Commission is, therefore, of opinion that the time has come when it is desirable to make a treaty limiting these diversions. * * * Therefore this Commission recommends that a treaty be had between the United States and Great Britain, in framing which, it should be recognized that * * *

Permanent or complete diversions of such waters are wrong in principal, and, therefore, should hereafter be absolutely prohibited. The diversions by the Chicago drainage canal should be limited to the use of not more than 10,000 cubic feet per second. * * * This would give an apparent advantage to Canadian interests, but as the diversion is not of serious injury to the Falls and does not materially affect the interests of navigation, it is more than counter-

balanced by the complete diversion of 10,000 cubic feet by way of the Chicago drainage canal to the Mississippi River.

On May 3, 1906, the International Waterways Commission, by report signed by all members, made a report as follows (proceedings I. C. W., 339):

"The Commission has made a thorough investigation of conditions existing at Niagara Falls and the two sections have presented reports to their respective governments setting forth these conditions, to which attention is invited. The following views and recommendations are based upon a careful study of the facts and conditions set forth in these reports. * * *

2. While the Commission are not fully agreed as to the effect of diversions of water from Niagara Falls, all are of the opinion that more than 36,000 cubic feet per second on the Canadian side of the Niagara River, or on the Niagara Peninsula, and 18,500 cubic feet per second on the American side of the Niagara River, including diversions for power purposes on the Erie Canal, cannot be diverted without injury to Niagara Falls as a whole.

[fol. 313] 3. The Commission, therefore, recommends that such diversions, inclusive of water required for domestic use or the service of locks in navigation canals, be limited on the Canadian side to 36,000 cubic feet per second, and on the United States side to 18,500 cubic feet per second (and in addition thereto, a diversion for sanitary purposes, not to exceed 10,000 cubic feet per second, be authorized for the Chicago drainage canal), and that a treaty or legislation be had limiting these diversions to the quantities mentioned.

The effect of the diversion of water by the Chicago drainage canal upon general navigation interests of the Great Lakes' system will be considered in a separate report. * * * The following principles are suggested * * *:

Permanent or complete diversions of navigable waters or their tributary streams should only be permitted for domestic purposes and for the use of locks in navigation canals."

On January 4, 1907, the International Waterways Commission made a special report, signed by all the members, entitled:

"The Chicago Drainage Canal—Joint Report of the International Waterways Commission."

Among other things in said report, the said Commission stated:

"There appears to be a tacit general agreement that Chicago needs, or will need about 10,000 cubic feet of water per second for sanitary purposes and that the city should have it without further question. * * * We therefore recommend that the government of the United States prohibit the diversion of more than 10,000 cubic feet per second for the Chicago drainage canal."

[fol. 314] After the evidence was presented in this case, the representatives of The Sanitary District succeeded in obtaining an inspection of the papers showing the negotiations between the United States and Great Britain, which led up to the treaty. The Secretary of State gave The Sanitary District copies of certain of the papers but would not allow copies of all the papers to be obtained. It appears that there was before the Secretary of State the various reports of the International Waterways Commission concerning the diversion of waters at Niagara Falls. The Secretary of State gave the Foreign Relations Committee of the United States Senate a memorandum concerning the treaty when it was before the Senate for ratification with reference to the diversion of waters at Niagara Falls and the diversion at Chicago. The said memorandum stated:

"The waters of Lake Michigan do not come within the definition of boundary waters, as defined in the preliminary article of the treaty, and it will be noted that in Article 1 of the treaty the waters of this lake are not included among the boundary waters of the Great Lakes system but are covered by special provision in the second paragraph of that article. * * * Attention is called to the express provision in this article that it shall not apply to cases already existing which would seem to cover, and was certainly intended to cover, the Canal system at Chicago. * * * The treaty, therefore, recognizes that the settlement of the question of the use of waters of Lake Michigan is purely a domestic question and leaves undisturbed the governmental rights of the United States with respect to it."

We are also advised that the Secretary of State, when he appeared [fol. 315] before the Foreign Relations Committee of the Senate, stated that the reason for allowing Canada 36,000 cubic second-feet of diversion of water at Niagara Falls, was because of the 10,000 second-feet of diversion at Chicago. This may be verified by reference to the proceedings of the Foreign Relations Committee of the United States Senate.

(6) The United States, by the Secretary of War, has consented to the reversal of the current and flow of the Chicago River, the south branch thereof and the west fork, and to the changing, if any, of the navigable capacity of the Chicago River and its branches in the respect and to the entire extent which has been or will be accomplished by the withdrawal of ten thousand cubic second feet of water from Lake Michigan. The main channel of the Sanitary District was opened and placed in operation on January 17, 1900. The waters of Lake Michigan were then drawn through it by way of the Chicago River and the branches mentioned. The channel was opened pursuant to consent of the Secretary of War by permit dated May 8, 1899. This permit was without limitation as to the amount of withdrawal or diversion, except that the limitation thereon would be the flowage capacity of the main channel of the District, which is in excess of ten thousand second feet. The permit of May 8, 1899, without the preambles thereto, is as follows:

"Now, therefore, the Chief of Engineers having consented thereto, this is to certify that the Secretary of War hereby gives permission to the said Sanitary District of Chicago to open the channel constructed and cause the water of Chicago River to flow into the same, subject to the following conditions:

[fol. 316] 1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action and that this permit shall be subject to such action as may be taken by Congress.

2. That if at any time it becomes apparent that the current created by said drainage work in the south and main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its south branch.

3. That the Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago River."

The conditions, it will be observed, of said permit related only to the future action of Congress, current in the Chicago River and the payment of damage to property resulting from any current in said river. Work was commenced upon the construction of the main channel of the District in 1891. The District was organized in 1889. The Sanitary District Act specifies the sort of a channel which should be constructed across the continental divide to form an outlet for the sewage and drainage within the territorial limits of the District. Congress was notified by reports of the Chief of Engineers in each year, from the beginning of the construction of the channel, not only of the plans of the District for the construction of said channel and its operation and withdrawal of water for such purposes, but also [fol. 317] of the progress of the work. In 1895 the Secretary of War appointed a commission of engineers, of which General Poe was chairman, to investigate the subject of the effect of the withdrawal upon lake levels of ten thousand cubic seconds feet of water. This commission made a report in the year 1895 to the effect that the levels of the lakes would be lowered approximately six inches by said diversion. In 1896, and from that time on, various permits were issued by the Secretary of War to the Sanitary District for the construction of various works in the Chicago River, necessary to carry out the District's plans for the diversion. Finally, as before stated, after thorough investigation by the Chief of Engineers and his assistants and the recommendation of the Chief of Engineers, the permit of May 8, 1899, was issued. Thereafter the channel was opened. The condition of the permit of May 8, 1899, concerning the current in the Chicago River, was inserted because of the then tortuous narrow and shallow Chicago River channel.

It was considered that it would be necessary, in order for the District to withdraw the amount of water desired through the river channel, that the flowage capacity of same would have to be enlarged. It was therefore not long after the channel was opened that it was found that an excessive current was created. Therefore, the District made plans in the year 1900 for the widening of the Chicago River, the south branch and west fork thereof to its junction with the northern terminus of the main channel, so that the channel would have a width through the entire course of not less than two hundred feet and a depth of not less than twenty-six feet in the center. The channel at that time was only seventeen feet deep. It [fol. 318] was necessary also to reconstruct and replace bridges across the river. These plans were submitted to the Secretary of War and the purpose of The Sanitary District to deepen and widen the Chicago River was stated and a permit was issued by the Secretary of War to The Sanitary District to make all changes necessary and the specific changes above set forth. Prior to the time when the said work of deepening and widening the river was commenced and after the channel was opened and placed in operation, the Secretary of War had limited the permit of May 8, 1899, by specifying that the flow or withdrawal should not exceed two hundred and fifty thousand cubic feet per minute. This limitation was placed solely because of the current in the Chicago River and it was so expressed in the permit. It is upon this permit that the Government is now seeking the injunction. Thereafter, The Sanitary District deepened and widened the river, rebuilt and replaced bridges pursuant to the permit of the Secretary of War, and has expended, in order to remove the cause for the limitation of two hundred and fifty thousand cubic feet per minute, upwards of thirteen million dollars. The cause and the reason for the limitation of the flow to the amount named has been removed and, therefore, the limitation becomes ineffective.

April 21, 1891, the Board of Trustees of The Sanitary District passed a resolution in regard to the use of the Chicago River and a certified copy thereof was sent to the Secretary of War. The resolution is as follows:

"Resolved that this Board hereby ordains that The Sanitary Dis- [fol. 319] trict of Chicago, do, forthwith, enter upon, use, widen, deepen and improve the Chicago River from its mouth at Lake Michigan to the south branch thereof and also the south branch thereof together with the south and west forks thereof so as to make the same a proper and sufficient supply channel for the main channel heretofore surveyed from the Chicago River to Joliet and further, that the acting Chief Engineer be and he is hereby directed immediately to investigate and report upon the capacity of said river and its said south branch and forks for that purpose, and also as to any changes that should be made therein and that a copy of this resolution, certified by the clerk be, forthwith, transmitted to the mayor and common council of the City of Chicago and the Secretary of War of the United States."

Congress, the Secretary of War, Chief of Engineers and his various assistants have had knowledge and notice of the plans and purposes of The Sanitary District in the construction of its works for diversion purposes and in the use of the waters of Lake Michigan for the operation of such works. There has been an acquiescence and at least a tacit agreement that the amount which The District needs, up to ten thousand second feet, would not be limited and that the diversion for sanitary purposes was recognized as being a paramount and primary use. The treaty between the United States and Great Britain with reference to Canadian boundary waters recognizes that the use for sanitary purposes is first and paramount to the use for all other purposes.

The Illinois and Michigan canal was constructed pursuant to Act of Congress of March 2, 1827, "to unite the waters of the Illinois River with those of Lake Michigan." Section 16 of the Act of Jan-
[fol. 320] uary 9, 1836, the General Assembly of Illinois provided that the canal should "be supplied with water from Lake Michigan and such other sources as the Canal Commissioners may think proper." The Supreme Court of the United States, in Missouri v. Illinois, 200 U. S. 495, 526, concerning the effect of the Congressional and State Acts, said:

"Some stress is laid on the proposition that Chicago is not on the natural watershed of the Mississippi, because of a rise of a few feet between the Desplaines and the Chicago rivers. We perceive no reason for distinction on this ground. The natural features relied upon are of the smallest. And if, under any circumstances, they could affect the case, it is enough to say that Illinois brought Chicago into the Mississippi watershed in pursuance not only of its own statutes but also of the acts of Congress of March 30, 1822, * * * and March 2, 1827, * * * the validity of which is not disputed."

From the time the Illinois and Michigan canal was placed in operation, water has been withdrawn through it from Lake Michigan, not only for navigation purposes, but also for sanitary purposes. The withdrawal for sanitary purposes increased as the sanitation needs of Chicago required it. In 1873 the channel of the Illinois and Michigan canal was deepened at the expense to Chicago of three million dollars in order to increase the withdrawal and thereby cleanse the Chicago River. In 1884 pumps were installed at Bridgeport to accomplish a greater withdrawal. The Sanitary District Act and the works constructed thereunder accomplished the replacement of the old Illinois and Michigan canal by the main channel of The Sanitary
[fol. 321] District. This was so held in the case of Mortell v. Clark, 272 Ill. 201, 213.

(7) The diversion of at least 10,000 cubic second-feet of water from Lake Michigan is essential for the sanitary needs and requirements of the population within the limits of The Sanitary District, which includes that of the City of Chicago and its suburbs, comprising a population of approximately 3,000,000 people. The primary

purpose of The Sanitary District is to construct and operate works to provide a pure drinking water supply for this population. The plans for the works of The Sanitary District were formulated and recommended by a commission of engineers, pursuant to an ordinance of the City of Chicago, known as "Drainage and Water Supply Commission." This commission studied the matter for two or three years and finally recommended the diversion of the drainage and sewage of Chicago and its environs to the Desplaines River, together with a sufficient amount of water from Lake Michigan (20,000 cubic feet per minute for each 100,000 population) to oxidize the sewage and waste. This Commission's report was made in 1887 and The Sanitary District Act was passed pursuant to the recommendations of that Commission at the next session of the Legislature, and the District has expended upwards of $100,000,000 in the construction of these works. They have accomplished practical results. There was not at the time the Commission made its report, and there has not been since that time, any other practical method that could have been adopted to accomplish the purpose of these works—namely, the protection of the water supply. The record in this case [fol. 322] shows that the art of artificially purifying sewage has been for years, and is now, in a state of uncertainty, and there is no plan for artificially purifying sewage that engineers agree is feasible and practical, and will with any certainty serve for a considerable period of time in the future—and this is particularly true when dealing with great metropolitan populations.

The basis, therefore, of The Sanitary District's diversion works is the reversal at all times of the Chicago River, into which a large amount of sewage is emptied from sewers serving the people of Chicago and its suburbs. The maximum run-off of the Chicago River drainage area is 10,000 cubic second-feet. Obviously, if the capacity of the main channel of the District were less than 10,000 second-feet, the Chicago River would flow into Lake Michigan at certain flood times. The withdrawal of water from Lake Michigan must, therefore, be the same amount, because it would be impossible, if the flow were limited to 4,167 feet, or any amount materially below the 10,000 second-feet, to change the flow from the limited amount to the maximum run-off of the drainage area in time to keep the water from going into Lake Michigan. This is demonstrated by testimony of witnesses in this case and it is recognized as a fact by the report of Col. Warren, Division Engineer of the Lakes Division, above mentioned. The limitation of the flow to 4,167 second-feet, or any amount materially less than 10,000 second-feet, would, therefore, require the absolute and complete purification of all sewage within the limits of the District, so that if any effluent found its way into Lake Michigan, it would not affect the water supply.

[fol. 323] There was presented in this case estimates of the cost of constructing artificial purification works to completely purify the sewage and drainage. These estimates were made in the year 1913. The total cost of constructing these works, which would require a great number of years to complete, was from $75,000 000 to $100,-

000,000. The figures were made with reference to the cost of materials, labor, etc., as of the year 1913. Since that time the cost of labor and materials for similar works has increased approximately 100 per cent, so that to install the works which would be made necessary by reason of the limitation of the flow to 4,167 second-feet, would be from $150,000,000 to $200,000,000. The cost of operating and maintaining these works annually was also estimated, and the estimates were upwards of $5,000,000 per annum. The annual operating and maintenance cost would now, according to present prices of labor and materials, much exceed that amount.

It is also shown in the record in this case that it would be impossible for the District or this community to raise the money necessary to construct these works within any reasonable time, unless constitutional amendment should permit greater bonding power.

In addition to the amount which the District would be compelled to expend by virtue of the limitation of flow to 4,167 second-feet, it would lose the greater portion of the investment that it has already made in the present diversion works.

Furthermore, it is probable that any works which the District might install for the purification of sewage and drainage would, within a very short time, have to be discarded and thrown aside for [fol. 324] some other works upon a different plan. Indicative of the changes in the art of artificially purifying sewage that have taken place we refer to the fact that it was only five years ago that most sanitary engineers believed that the best method to be used was the Imhoff Tank system. In these tanks a certain amount of sewage was allowed to settle and the effluent drawn off to run through what are called "sprinkling filters," by which the effluent from the Imhoff tank was, by means of a nozzle, sprayed over crushed rock of several feet in thickness. Lately, sanitary engineers have reached the conclusion that such method is not proper but that what is known as the "activated sludge" system should be used. This system contemplates the passing of the sewage and drainage at low velocities through tanks, which tanks are provided at the bottom with perforations so that a vast amount of air may be pumped through the sewage and thereby the sewage be purified.

If the District were limited now to the withdrawal of 4,167 second-feet, at many times during the year the Chicago River would flow into Lake Michigan, carrying with it a vast amount of sewage. At and prior to the time the Drainage Canal was opened and placed in operation, the death rate per year from typhoid fever was 75 per 100,000 population. Occasionally there would be epidemics, when the rate would be 190 per 100,000. Since the opening of the Drainage Canal there has been a steady reduction in the death rate per year from typhoid fever, with no epidemics, so that now the death rate from typhoid fever is less than 1 per annum per 100,000 of population. According to Hazen's theorem, where there is an increase of 1 per annum in death rate from typhoid fever, there is an increase of 3 from other kindred disease; and the same theorem applies con- [fol. 325] versely to a decrease. The limitation to 4,167 second-feet

would produce intolerable conditions in the Illinois River, because of the fact that the principal amount of the sewage of Chicago and its suburbs would be delivered to the Desplaines and Illinois Rivers without the necessary pure water for oxidization and purification purposes. All fish life would be destroyed throughout the entire course of said river and the fish industry along the Illinois River is one of the principal industries of the state. The conditions above mentioned that would result from the limitation of flow to 4,167 second-feet would continue until works were installed to practically purify a very large portion of the sewage and drainage arising within the limits of The Sanitary District, and it would continue to a certain extent until the works were installed to purify all sewage and drainage.

8. Since the drainage Canal was opened, January 17, 1900, all boats that were then navigating the Great Lakes and its connecting waters are not interfered with in any respect, by a less depth due to lowering of lake levels. All boats which the United States claims are affected—those owned by the Pittsburgh Steamship Co., a subsidiary of the United States Steel Corporation—were constructed since that time. All the critical points of navigation of the Great Lakes have been, since the opening of the Drainage Canal, deepened or improved, and the record in this case shows that the reference plane for the improvement of 1903, which included practically all the connecting channels, was made approximately 6 inches lower because of the diversion at Chicago—so that, the navigation interests have not been injured. They have the same depth of water that they would have had if the diversion had not existed.

[fol. 326] 9. The Sanitary District here and now offers and agrees to pay to the United States the amount of money necessary to construct, operate and maintain the compensating works which will off-set or compensate for any damage due to the diversion at Chicago. These works the Federal engineers have said may be installed and will accomplish the purpose named. If they were installed and placed in operation, the only ground of the Government for seeking the injunction here would be removed. The expense would be practically nothing as compared with the financial burden that would be placed upon the District if it is enjoined from withdrawing more than 4,167 second-feet of water, or any amount materially less than 10,000 second-feet. The only thing that the Government would have to do in order to accomplish the installation of the works would be to provide for their construction, operation and maintenance. The suggestion for modification of the opinion and direction of the court with reference to the decree in these cases herein made points out the plain practical solution of this problem.

The facts above mentioned are all found in the record, except those that have arisen since the closing of the taking of testimony (1914) or those discovered since—negotiations leading up to Canadian Boundry water treaty.

Respectfully submitted, —— ——, Attorney for the Sanitary District of Chicago. —— ——, of Counsel.

[fol. 327] EXHIBIT A TO MOTION

An ordinance of the Board of Trustees of the Sanitary District of Chicago offering and agreeing to defray the expense of the construction of works in one or more of the outlets of the Great Lakes to compensate for any diminishing levels of the Great Lakes and connecting waters due to the diversion of 10,000 cubic feet of water per second from Lake Michigan by the Sanitary District of Chicago and authorizing the attorneys of the Sanitary District in the suits pertaining to said diversions now pending in the District Court of the United States for the Northern District of Illinois, Eastern Division, to make and present such offer and agreement in open court.

Whereas, there are now pending in the District Court of the United States, for the Northern District of Illinois, Eastern Division, two suits in equity instituted by the United States against The Sanitary District concerning the withdrawal of water from Lake Michigan by The Sanitary District of Chicago. The first suit was instituted in the year 1908 and pertains particularly to the construction and operation and withdrawal of water for the operation of the Calumet Sag Channel, an adjunct of the main channel of The Sanitary District of Chicago. The second suit was instituted in the year 1913 and seeks to enjoin The Sanitary District from withdrawing from Lake Michigan, through its various channels, including the Calumet Sag Channel then and now under construction, [fol. 328] more than 4,167 cubic feet of water per second. The said suits have been tried together and submitted together upon briefs; and,

Whereas, the Honorable Kenesaw M. Landis, one of the Judges of said District Court of the United States, for the Northern District of Illinois, Eastern Division, before whom said cases have been pending, did recently render an opinion or direction for the entry of a decree in said cases, in substance, to enjoin The Sanitary District of Chicago, defendant in said cases, from withdrawing from Lake Michigan more than 4,167 cubic feet of water per second; and

Whereas, various reports have been submitted purusuant to acts of The Congress of the United States by the Engineer Corps of the U. S. A., finding that the claim of injury to navigation arising from the lowering of lake levels because of the diversion from Lake Michigan of water at Chicago to the extent of 10,000 cubic feet of water per second, may be compensated for by the construction of fixed weirs or works of similar character, or by the construction and operation of movable dams in the St. Clair, Niagara and St. Lawrence Rivers, or one or all of them, and that the expense of constructing said fixed weirs would, at the time the report was made, not exceed $475,000; and it was recommended that if The Sanitary District of Chicago should defray the expense of constructing such works, then they should be maintained by and at the expense of the

United States; and, if such works were constructed and placed in operation, thereby the ground of the United States for securing the injunction herein would be removed; and,

[fol. 329] Whereas, it is the opinion of the Board of Trustees that if The Sanitary District is enjoined from taking more than 4,167 cubic feet of water per second from Lake Michigan for sanitary purposes, it will be necessary to expend, in the construction of works to artificially purify sewage, supplement and aid the works diverting 4,167 cubic second feet of water upwards of $150,000,000, and the operation and maintenance of the same will exceed upwards of $5,000,000 per annum; and it is, further, the belief of the Board of Trustees of The Sanitary District of Chicago that it is doubtful whether such works, with said limited withdrawal of 4,167 cubic second feet of water will provide for the people of The Sanitary District of Chicago, which includes the population of Chicago and its environs, a safe drinking water supply, for the reason that it would be impossible, with said limited withdrawal, to keep the Chicago River at all times reversed so that it would not flow into Lake Michigan, carrying with it a large amount of sewage and drainage, and it is doubtful whether such purification works would accomplish practical results.

Now, therefore, be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. The Sanitary District of Chicago does hereby offer and agree to defray the expense, and pay to the United States Government the cost, of constructing and maintaining works to be installed at the outlet or outlets of any of the Great Lakes to compensate for any diminishing levels of the Great Lakes and connecting [fol. 330] waters, due to a diversion or withdrawal from Lake Michigan of 10,000 cubic feet of water per second by The Sanitary District of Chicago through its various channels and diversion works in the event The Sanitary District is not enjoined from diverting from Lake Michigan less than 10,000 cubic seconds feet of water.

Section 2. The said offer and agreement contained in Section 1 hereof is intended to embrace and cover not only the expense of constructing and maintaining fixed weirs or dams described in the report entitled "Final Report of Waterways from Lockport to the Mouth of the Illinois River," House of Representative's Document No. 762, 63rd Congress, 2d Ses-ion, but also any other works of similar character that may be planned or provided for by the Congress of the United States or by competent Governmental authority, or works known as "regulating works," consisting of movable dams or dams that may be moved from time to time, that may be planned or provided for by The Congress or other competent authority—such works having for their purpose compensation for any diminishing levels of the Great Lakes or connecting waters due to a diversion at Chicago of 10,000 cubic second feet of water; and the said The Sanitary District of Chicago offers and agrees to pay to the United States the expense of constructing and maintaining such works when-

ever the United States shall provide for such construction and make request for the payment of the amount of money necessary to construct and maintain the same.

Section 3. The attorneys for The Sanitary District of Chicago in [fol. 331] said two suits above described, wherein the United States is complainant and The Sanitary District of Chicago is defendant, on behalf of The Sanitary District of Chicago, are hereby authorized, empowered and directed to present and make said offer in open court in said causes, or in any other manner that the said attorneys may deem proper.

Section 4. The preambles to this Ordinance are hereby made a part of same and this Ordinance shall take effect and be in force from and after its passage.

Approved:
William J. Healy, President of the Sanitary District of Chicago.

[Title omitted]

NOTICE

To Honorable Charles F. Clyne, United States District Attorney for the Northern District of Illinois, attorney for the complainant:

Please take notice, That on Monday morning, the 12th day of [fol. 332] July, A. D. 1920, at the opening of court, or as soon thereafter as counsel can be heard, we shall appear before Honorable Kenesaw M. Landis, one of the judges of said court, in the Federal building, Chicago, Ill. in the room usually occupied by him as a court room and present the foregoing motion for modification of oral opinion of said court and oral direction of the court with reference to the entry of the decree herein, at which time and place you may be present if you see fit.

——— ———, Attorney for Defendant.

[fol. 333] And the following is an amendment to said motion, filed herein:

[fol. 334] [Title omitted]

[fol. 335] IN THE DISTRICT COURT OF THE UNITED STATES FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

AMENDMENT TO MOTION FOR RECONSIDERATION OF ORAL OPINION AND ORAL DIRECTION OF THE COURT CONCERNING THE FORM OF DECREE IN SAID TWO CAUSES, TOGETHER WITH GROUNDS OF SAID MOTION

Now comes the Sanitary District of Chicago, by William F. Mulvihill, Morton S. Cressy and Edmund D. Adcock, its attorneys and amends its "Motion for Reconsideration of Oral Opinion and Oral Direction of the Court Concerning the Form of Decree in said two Causes, together with Grounds of said Motion," by inserting, at page 27 of said printed motion, and at the end of paragraph No. 7 thereof, a new paragraph known and called paragraph No. 7½ as follows:

"7½. On, to wit, August 7, 1919, the Board of Trustees of the Sanitary District of Chicago duly adopted an ordinance, which ordinance was approved by the President of said Board, entitled: [fol. 336] 'An ordinance of the Board of Trustees of the Sanitary District of Chicago laying out and adopting a program for the construction and operation of works for the purification of or the removal of solids and organic and inorganic matter from sewage, trade waste, offall and other organic and inorganic matter so that within the period of the next twenty-five years not more than fifty per ceht of the amount of said sewage and waste that is now passing into the Desplaines River from the main channel of the Sanitary District will at the end of such period find its way into said river. Such works are to supplement those constructed or in process of construction for the diversion of sewage and drainage arising within the limits of the Sanitary District of Chicago.'"

The said ordinance, exclusive of the preambles, is as follows:

"Be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. To supplement the works of the Sanitary District of Chicago now constructed or in the process of construction for the diversion of sewage or drainage, and to aid said works in better accomplishing the purpose for which they were constructed, the Sanitary District does hereby lay out and adopt a program for the construction and operation of works for the purification of sewage or the removal of organic or inorganic matter from human sewage

and the removal of trade wastes and other wastes and for the carrying on of such work at such a rate as continuously after the lapse of four years to diminish the amount of sewage including all wastes passing into the Desplaines River by way of the Main Channel of the Sanitary District of Chicago, so that within the period of twenty-five years such purification works shall be constructed and in operation, that the amount of such raw sewage and wastes so passing into [fol. 337] said Desplaines River shall be at least fifty per cent less than that passing now.

Sec. 2. The Chief Engineer and the Attorney of the Sanitary District are hereby directed to take such steps as may be necessary to carry forward the foregoing program, and the Chief Engineer is directed to report to such officers of the United States and the State of Illinois as may be interested, the progress made from time to time in carrying out said program.

Sec. 3. The foregoing preamble to this ordinance is hereby adopted and made a part of same.

Sec. 4. This ordinance shall be in full force and effect from and after its passage and adoption."

In 1921 the General Assembly of Illinois amended the Sanitary District Act so as to specifically authorize the Board of Trustees to construct the works and carry out the program for sewage purification, as set forth in the foregoing ordinance. The said ordinance was passed by the Board of Trustees of the Sanitary District of Chicago after negotiations with the Division Engineer at Chicago, representing the Chief of Engineers of the United States Army, and a draft of said ordinance was submitted to said Division Engineer at Chicago before it was passed, and said draft of ordinance was approved. It was stated by the said Division Engineer that the passage of said ordinance, and the carrying out of the program for sewage treatment, so mentioned in said ordinance, would be satisfactory to the United States, as the final solution of the problems involved in the controversy between the United States and the Sanitary District. The Sanitary District of Chicago has, since the adoption of said ordinance by its Board, carried out the program in said ordinance mentioned, as laid out, and is now constructing sewage treatment [fol. 338] works. Said sewage treatment works now constructed, or under construction have, or will cost many millions of dollars and the Sanitary District has planned the construction of further works to carry out in good faith the program for sewage treatment, so outlined in said ordinance.

William F. Mulvihill, Attorney for the Sanitary District of Chicago, Defendant. Morton S. Cressy, Edmund D. Adcock, of Counsel.

[fol. 339] Thereupon, on July 12, 1920, the said motion entitled "Motion for Reconsideration of Oral Opinion and Oral Direction of

the Court Concerning the Form of Decree in said two Causes, together with Grounds of Said Motion" was presented to the Honorable Kenesaw Mountain Landis, Judge of the District Court of the United States, for the Northern District of Illinois, Eastern Division, and partly heard and argued; and thereafter Judge Landis resigned his position as Judge of said Court and ceased to become Judge thereof on March 1, 1922. No further proceedings were had before Judge Landis in said cause between the date of the presentation of said motion and its being partly heard and argued before him and said March 1, 1922, when Judge Landis left the bench; and, thereafter, the cause was assigned to Honorable George A. Carpenter, Judge of [fol. 340] said Court. Thereafter, on June 18, 1923, the Court entered the following order:

ORDER REFUSING OFFER TO CONSTRUCT CERTAIN WORKS

"The motion presented herein on the 12th day of July, 1920, by the defendant, asking that the defendant be not enjoined or restrained from withdrawing from Lake Michigan less than ten thousand (10,000) cubic seconds feet of water, and in connection with said motion an offer was made to pay cost of constructing and maintaining such works and might be provided by complainant to off-set for the lowering of the surface elevations of Lakes Michigan, Huron, St. Claire, Erie and Ontario, due to a diversion of said amount by the defendant at Chicago, is hereby denied, and the said offer is refused."

To the entry of which order the defendant duly excepted.

Thereupon, on June 18, 1923, the Court entered the following order and decree:

DECREE FOR INJUNCTION

"That the defendant, the Sanitary District of Chicago, its Board of Trustees, officers, agents, attorneys, representatives, employees and servants, and all other persons acting or claiming or assuming to act under its authority, be, and they hereby are, and each of them hereby is, enjoined from diverting or abstracting any waters from Lake Michigan over and above or in excess of 250,000 cubic feet per minute.

The operation of this injunction is hereby stayed for a period of [fol. 341] six months to enable the defendant to present the record herein to the Supreme Court of the United States."

To the entry of which order and decree the defendant duly excepted.

ORDER SETTLING CERTIFICATE OF EVIDENCE

The foregoing is all the evidence and proceedings had in the above entitled consolidated cause, and inasmuch as the matters above set forth do not fully appear of record in this suit, the defendant tenders this certificate of evidence and prays that the same may be certified under the hand and seal of the Judge of this Court and thereupon made a part of the record in such cause, and it is certified accordingly, this 29th day of June, A. D. 1923.

George A. Carpenter, Judge. (Seal.)

[fol. 342] [File endorsement omitted.]

[fol. 343] IN THE DISTRICT COURT OF THE UNITED STATES FOR THE NORTHERN DISTRICT OF ILLINOIS, EASTERN DIVISION

[Title omitted]

PRÆCIPE FOR TRANSCRIPT OF RECORD—Filed June 29, 1923

To the Clerk of said District Court:

Please prepare transcript of record in the above entitled cause and insert therein the following:

1. The bill of complaint in case number 29019.

2. The answer of the defendant thereto.

3. Exceptions of the complainant to answer of the defendant.

4. Bill of complainant in case number 114.

5. Answer of the defendant to said bill.

6. Certificate of evidence.

8. Stipulation of June 29, 1923.

9. Order of June 18, 1923, consolidating two causes number 114 and 29019.

10. Order of June 18, 1923, denying defendant's motion of July 12, 1920.

11. Final decree entered June 18, 1923.

12. Petition and order for appeal to the Supreme Court of the United States.

13. Assignment of Errors.

14. Order to make part of the record all of the evidence taken in [fols. 344 & 345] the case in the exact words of the witnesses.

15. Appeal bond.

16. Copy of this præcipe.

17. Order entered substituting printed record for typewritten record as filed by the Commissioner.

18. Order extending time to file transcript of record.

19. Copy of Motion to strike part of answer Feb. 18, 1914.

20. Opinion of Judge Carpenter June 18, 1923.

Clyde L. Day, Edmund D. Adcock, Attorneys for Defendant.

[File endorsements omitted.]

[fols. 346 & 347] Northern District of Illinois,
Eastern Division, ss:

Clerk's Certificate

I, John H. R. Jamar, Clerk of the District Court of the United States for the Northern District of Illinois, do hereby certify the above and foregoing to be a true and complete transcript of the proceedings had of record made in accordance with Præcipe filed in this Court in the cause entitled The United States of America vs. The Sanitary District of Chicago, No. 114, in Equity, as the same appear from the original records and files thereof now remaining in my custody and control.

In testimony whereof, I have hereunto set my hand and affixed the seal of said Court at my office, in the City of Chicago, in said District, this 15th day of August, A. D. 1923.

John H. R. Jamar, Clerk. (Seal of Dist. Court U. S., Northern Dist. Illinois.

[fol. 348] In the District Court of the United States

[Title omitted]

Certificate of Evidence

Further proceedings in the above-entitled cause before Samuel M. Morgan, Commissioner, on Wednesday April 25, 1923, at 10.30 o'clock a. m., at the Rookery Building, Chicago, Illinois, pursuant to stipulation.

Appearances: Mr. Edwin A. Olson, U. S. Attorney; Mr. Joseph B. Fleming, Special Assistant to the Attorney General, on behalf of the Complainant, Mr. Clyde L. Day, Mr. George F. Barrett, Mr.

Louis J. Behan, and Mr. Edmund D. Adcock, on behalf of the Defendant.

[fol. 349] Mr. Adcock: I will offer in evidence a certified copy of an ordinance passed by the Board of Trustees of The Sanitary District on August 7, 1919.

Mr. Fleming: The record will show my objection.

Mr. Adcock: I think there is a stipulation in the record to the effect that objections as to materiality, relevancy and competency may be preserved, without making the formal objection at the time. It may be presented at the hearing or any other time. Proper objections to the form of question and answer are to be taken at the time the testimony or evidence is presented, in order to avoid the necessity of taking it over again.

Mr. Fleming: If that is preserved, that is all I want.

Mr. Adcock: I offer that copy as Pearse Exhibit 1 of this date.

(Certified copy of ordinance passed by the Board of Trustees of The Sanitary District on August 7, 1919, offered in evidence, was marked Pearse Exhibit 1, April 25, 1923, and is hereto attached.)

Mr. Adcock: I offer a certified copy of an ordinance of the Board of Trustees of the Sanitary District of Chicago, passed by the Board [fol. 350] at a meeting held on July 8, 1920, as Pearse Exhibit 2 of this date.

(Certified copy of ordinance of Sanitary District offered in evidence, was marked Pearse Exhibit 2, April 25, 1923, and is attached hereto.)

Mr. Adcock: I offer in evidence as Pearse Exhibit 3 of this date a copy of a letter dated May 24, 1921, from the Division Engineer at Chicago, Colonel William V. Judson, Corps of Engineers, to the Chief of Engineers of the United States Army at Washington D. C. This is subject to verification as to correctness of the copy that is offered.

(Letter of Colonel William V. Judson dated May 24, 1921, offered in evidence was marked Pearse Exhibit 3, April 25, 1923, and is hereto attached.)

[fol. 351] LANGDON PEARSE, a witness called on behalf of the defendant, was first duly sworn by the Commissioner, and testified as follows:

Direct examination.

By Mr. Adcock:

Q. Your name is Langdon Pearse?
A. Yes, sir.
Q. You reside where?
A. In Winnetka, Illinois.

Q. What connection if any have you with the defendant, the Sanitary District of Chicago?

A. I have been employed with The Sanitary District of Chicago in various capacities since March 1st, 1909; at present in the position of Sanitary Engineer, in charge of the sanitary engineering work of the District.

Q. Will you state your education, and generally your experience; what you have done in the engineering world?

A. I am a graduate of Harvard College with the degree of A. B. in 1899; and from the Massachusetts Institute of Technology, with a degree of Bachelor of Science in Civil Engineering; also Master of Science in Civil Engineering, of date 1902.

In the period between 1901 and 1909, at which time I became [fol. 352] connected with the Sanitary District, I was successively Levelman for the Massachusetts Harbor and Land Commission, on the Brockton Ship Canal; Assistant Engineer to the Charles River Dam Commission, under John R. Freeman; Assistant Engineer for the Commission on Additional Water Supply in New York City, known as the Herring-Burr-Freeman Commission; also as Personal Assistant to George C. Whipple in work for the Augusta Water District, Me., Cleveland and Jersey City; and also in connection with the suit of Missouri vs. Illinois.

From there, I was Assistant Engineer for the Improved Water and Sewage Works at Columbus, Ohio, involving the construction of a water filtration and softening plant; also sewage treatment; and also Assistant Engineer on the Greater Water Supply for the People's Water Company of Oakland, California, a water filtration project.

From 1909 to date, I have been successively assistant engineer, division engineer, and since 1907, sanitary engineer with the Sanitary District of Chicago, in charge of all sanitary work, involving the laboratory work covering chemistry and bacteriology, in connection with our testing stations, studies of the Canal and River, [fol. 353] as well as industrial wastes; the construction and operation of four Testing stations, respectively on domestic sewage at 39th Street and the Lake, packinghouse waste, tannery sewage and Corn Products sewage; the design and construction of intercepting sewers in size from six inches to twenty-two feet in diameter, including the North Shore Intercepting Sewer, the Stockyards Intercepting Sewer, the Calumet Intercepting Sewer, and the 52nd Avenue Sewer Outlet; the design of sewage pumping stations, known as the Evanston, Desplaines, Calumet, 95th treet stations, and also the remodeling of Lawrence Avenue and 39th Street; the design of sewage treatment works and other construction at Morton Grove, the so-called Calumet works at 125th Street and Cottage Grove Avenue, the Desplaines River Treatment Works, near the Subway Hospital in Broad view; Glenview Sewage Treatment Works, and the designs for the North Side Sewage Treatment Works.

I have further been in charge of the general operation of the Sewage Treatment Works, of which we now have three in operation, one at Morton Grove, one at Calumet, and one known as the Desplaines River.

In addition to these technical duties, I have also been in charge [fol. 354] of preparing special reports and data for the use of the Chief Engineer and others in different suits.

In addition to my duties with The Sanitary District, I have further served as a Consultant for the U. S. Public Health Service on stream pullution for the last three years; and in that connection served for the Sanitary District on a joint survey with the U. S. Public Health Service of the Illinois River, extending over a period of one year.

In my private capacity as a Consulting Engineer, I have executed the following works, in special partnership with George W. Fuller; designed and built the Evanston Water Filtration plant. As a member of the firm of Pearse, Greeley & Hansen, we designed and built the Decatur, Illinois Dam & Sewage Treatment Works; the Whiting, Indiana Water Filtration plant, and the Winnetka, Illinois Water Filtration plant.

And further, as engineer, have made reports for, designed and built works for the Sanitary District of Decatur, the North Shore Sanitary District, the Downers Grove Sanitary District, the Sanitary District of Champaign and Urbana; and in addition have made miscellaneous reports on industrial wastes for the Holland-St. Louis [fol. 355] Sugar Company, the Standard Oil Company of Indiana and others.

I am also a member of the American Society of Civil Engineers, and the American Institutute of Consulting Engineers.

Q. What studies have you made in regard to the sewage disposal problem of The Sanitary District?

A. I was first employed on the work in 1909, with the intent of making a complete and thorough investigation of the sewage treatment problem of The Sanitary District. I have been at that ever since.

I first went into the engineering details in the so-called 1911 report of Mr. Wisner, who was then Chief Engineer; and later in 1912 and 1914, I went into the matter again in connection with this particular law suit for Mr. Wisner. And further in 1919 and 1920, in connection with the report of the so-called Expert Commission composed of Eddy, Fuller and Hatton.

It was early evident that to unravel the sewage treatment problem, a close study was required, not only of the sewage from the human sources, but also of the wastes of industrial origin.

The study of the domestic sewage was begun by a testing station [fol. 356] at 39th Street and the Lake, operating on sewage coming from an area of over twenty-two square miles, and from a population of 270,000 and up. This was very free from industrial wastes. In this Station were tried all the practical methods of sewage treatment then known, including septic tanks, Imhoff tanks, biolytic tanks, sprinkling filters, etc.

Q. Just explain those different terms, what the methods are?

A. The difference between the different tanks mentioned is essentially one of construction as well as operation. By septic tanks, I mean the single story tank in which the solids deposited from the

sewage are allowed to accumulate, with cleaning at infrequent intervals.

By the Imhoff tank, I mean a double deck type of tank in which the upper chamber serves as a settling chamber, the solids passing through a trap into the lower chamber where they digest at leisure, the gases passing off through a separate vent, in order not to contaminate the sewage flowing through, which is settling.

The sludge from this tank may be drawn at intervals of two weeks, [fol. 357] in the warm weather; the storage capacity provided being from four to six months, according to the design.

The biolytic tank is a special device, in which all the sewage entering the tank comes in at the bottom and passes through the sludge deposit. This tank has been used only experimentally, and while it gave a remarkable reduction of sludge, it produced offensive odors and was therefore discontinued.

The sprinkling filters mentioned are beds of crushed stone, in the experimental work ranging from five to ten feet in depth, but usually in active work around six feet and a half, the stone being composed of one and a half to two inches in size. These beds are placed upon prepared underdrains to permit free drainage of the liquid trickling down through. The liquid is sprinkled upon the surface by nozzles spaced up 13½ feet on centers, operating intermittantly and dosing the beds at a rate of from two to five million gallons per acre per twenty-four hours.

Q. How was the station operated there at 39th Street?

A. The 39th Street Testing Station was operated from October 1909 to January 1915. The results that were obtained there indicated that with the more dilute sewage found in Chicago, liberal [fol. 358] provision for treatment, loadings, was required.

The value of the Imhoff tanks and sprinkling filters was clearly demonstrated.

Following the study of the domestic sewage, we entered upon an extended study of the Packingtown situation in January 1911. The preliminary investigation showed the lack of knowledge for handling such waste. Consequently a Testing Station was established in 1912, and operated until September 1918. These studies showed that the activated sludge process was the most promising of success on Packinghouse waste.

I might explain that the activated sludge process is a process in which the solids settling from the sewage are held back and conditioned by the blowing of air, so that in a period of about two weeks it has acquired the property of changing from the organic matter coming in the sewage to a more mineral form. It is essentially a biological process, involving the same principles as in the sprinkling filter, except that the films which are active and doing the work are held in suspension by air blown in at the bottom of the tanks, instead of the films being around the periphery of the stones in a bed above ground. The sludge is retained by settling tanks, returned to the [fol. 359] incoming sewage and then held in contact and in thorough mixture by the air blown in at the bottom of the tanks.

From day to day a certain amount of sludge can be removed from

the system, about one thousand pounds per million gallons of domestic sewage, and in the case of Packingtown about between three and four thousand pounds of dry solids per million gallons.

This sludge is higher in nitrogen than the usual sludge from Imhoff tanks or other processes.

Q. The activated sludge method is substantially a reversal of the sprinkling filter, isn't it? In the one you pump the air in, while in the other you disseminate it, so the air can get to it?

A. Yes, in that sense.

In connection with our packinghouse investigation, a thorough inspection was made of every packinghouse in the Sanitary District, the flow from each being gaged and analyzed before entering the sewer.

In 1911, all the packinghouses were examined. In 1917, the work was repeated, the flow of thirty-one houses being measured and analyzed in a period of about three months.

[fol. 360] The study of the tannery situation was begun in 1912. A recent investigation showed twenty houses all located on the North Branch of the Chicago River. After a number of inspections, a tannery testing station was established in December 1919, and operated up to December 31, 1922. In this the various processes applicable to handling tannery wastes were tried, including sprinkling filters and activated sludge. A survey of the industry was also made, house by house.

The Corn Products Refining Company plant at Argo was early recognized as an outstanding source of organic pollution. After some preliminary work, a testing station was established in 1921, by which the experiments have been conducted to date, using activated sludge and also a sprinkling filter. The flow of the plant has been measured, analyzed and correlated to the grind. This plant manufactures primarily starch and glucose, and is the largest of its kind in the world, grinding upwards of 75,000 bushels of corn every twenty-four hours.

Q. Are there any other sources of pollution than the ones you have mentioned; that is outside of the human sewage?

A. Yes, sir, there are other sources of pollution, which we have [fol. 361] investigated in a cursory way, which add to the load, but are not so important as those listed. Among these may be mentioned the Pope Beet Sugar factory, miscellaneous butterine factories, paint and glue works, gas works, paper mills and wire mills.

Q. Have you reached any conclusion as to the method to pursue in artificially treating these wastes and sewage?

A. Yes, sir.

Q. What is that conclusion?

A. The study I have made in the last fourteen years has led me to divide the Sanitary District into five main geographical projects, namely:

The Calumet, South of 87th Street.

The Southwest, South of the Canal and the river and North of 87th Street.

The West, north of the canal and river, and south of Fullerton Avenue in general, and the

North Side project, North of Fullerton Avenue.

In addition, there is the Desplaines River project.

Besides these five main projects, there are the Packingtown, Corn Products and Tannery industrial projects. The first two require [fol. 362] separate treatment plants distinct from the human sewage plants, whereas the tannery situation is to be combined with the North and West Side projects.

Besides the major projects outlined, there are and will be for many years small treatment units, plants for isolated villages such as Morton Grove, Glenview, Shermerville and the like, where the population is small and the distances are too great to warrant the construction of an intercepting sewer at present.

Q. Have you made any estimate of the population of the Sanitary District as it probably will be at different times in the future?

A. Yes, sir, I have made a careful study of the population in the Sanitary District from the United States census figures from the component parts of the census of 1890, 1900, 1910 and 1920. From the figures an estimate has been made of the future population of the District up to 1960. The growth of the various sewage treatment project areas has also been worked out in detail.

Q. Just state how you make those estimates of the future population.

A. We have plotted the populations as they have existed, with the [fol. 363] correction for the date, on paper, and then projected a curve on that.

We have further tested the ten year increment by the actual differences, taking into account the growth of the territory of the Sanitary District, and have arrived at the figures given in the table.

Q. Is that a usual method adopted by engineers in determining populations of the future in a metropolitan area?

A. Yes, sir, this method has been used and is one that is usual among engineers.

Q. You have there a table showing the population for the years 1890, 1900, 1910 and 1920.

A. Yes.

Mr. Adcock: I offer that in evidence as Pearse Exhibit 4 of this date.

(Table produced by witness for the years 1890, 1900, 1910 and 1920, offered in evidence, was marked Pearse Exhibit 4, April 25, 1923, and is hereto attached.)

Q. Have you a table which shows the populations for the future, 1930, 1940, 1945, 1950, 1955 and 1960, including also the year 1920?

A. Yes, sir, that table has been prepared. (Producing same).

[fol. 364] Mr. Adcock: I offer that in evidence as Pearse Exhibit 5 of this date.

(Table for the years 1920, '30, '40, '45, '50, '55 and '60, offered in evidence was marked Pearse Exhibit 5, April 25, 1923, and is hereto attached.)

Q. What was the total load upon the Main Channel in 1920, expressed in population, and what was the human population and the industrial load expressed in equivalent human population?

A. These loads are shown in the table which I have prepared based on the census populations and the projected population for the human load, and based upon our surveys for the industrial load expressed in equivalent population.

Q. And you have prepared an exhibit showing that?

A. Yes.

Mr. Adcock: I offer that in evidence as Pearse Exhibit 6 of this date.

(Table described by witness, offered in evidence, was marked Pearse Exhibit 6, April 25, 1923, and is attached hereto.)

Q. What estimates have you made covering the same propositions for the years 1930, 1940, 1945, 1950 and 1955? Have you prepared a table covering that?

[fol. 365] A. The estimates for the years following 1930, and up are given in the Exhibit 6, following the figures given for 1920, for the totals there expressed.

Q. How did you get at this proposition, what method did you use as shown on those tables?

A. The method by which I have arrived at the population equivalent of the industrial wastes is based on the dissolved oxygen required to oxidize the putrescible matter in sewage. Continued research over many years in the laboratory of the Sanitary District has shown this to be a reliable and accurate measure of the strength of sewage, inasmuch as it utilizes exactly the same biological activities which are effective in the stream. By stream I mean the Canal, Desplaines and Illinois Rivers.

Essentially, the test depends on mixing with the sample sufficient standard water saturated with dissolved oxygen to supply enough dissolved oxygen to oxidize the organic or putrescible material, in five, ten or twenty days, as the case may be, and leave a small amount of oxygen over at the end of a period.

The amount of dissolved oxygen required is expressed in parts per [fol. 366] million. For purposes of comparison, a ten day period has been chosen in our work, inasmuch as 90 per cent of the oxidation of the putrescible material is generally completed in sewage within that period. Such a test is called the Biochemical oxygen demand, and has been widely used by the U. S. Public Health Service, the Sanitary District and other research workers, as being more delicate and expressive than the old line chemical determinations. In some instances we have used nitrate of soda, added in known amounts, in place of dissolved oxygen.

The first step in the study of our sewage was to determine the amount of dissolved oxygen required per capita to oxidize the putrescible matter in human sewage. Prior to the work of the Sanitary District this figure had never been determined. Experiments were made on the sewage at 39th Street Pumping Station during

the year 1914. This sewage was chosen because a thorough inspection of the area tributary showed no industrial wastes likely to upset the tests.

On 179 days, hourly portions were collected during the twenty-four hours and daily composites were made. These were analyzed. The flow of the sewage was measured. The population tributary was [fol. 367] estimated. From the data the average figure was determined that 100 grams of oxygen are required per capita to properly oxidize the human sewage, or 0.22 pounds. Subsequently other research chemists confirmed this figure to me personally.

The next step was to determine the amount of putrescible material requiring oxidation from the different industries. This was done from time to time as follows:

The Packingtown and Union Stock Yards situation was investigated in the summer of 1917 between July 9, and October 6. At that time thirty firms were actively engaged in the packing and allied industries, in addition to the Stockyards. All of these houses were examined, and the flow gaged and analyzed from forty-one outlets, besides the public sewers, and certain outlets from the Stockyards. In all cases (except three of the smaller houses where the examination lasted two days) the sampling and gaging continued a week, night as well as day.

The flow was read as frequently as every ten minutes in most cases. For analysis, individual portions were taken every ten minutes and combined into hourly composites, which in turn were combined into [fol. 368] day or night composites, weighted according to the flow.

I mentioned the fact we made day and night composites, because there was a marked difference in the flow, in the strength day and night, as well as in the quantity.

From the determination of the biological oxygen demand and the flow, the total oxygen requirement was calculated. Based on the 0.22 pound per capita, the effect of the Stockyards and Packingtown was found to be practically 1,000,000 people. This investigation alone cost $5,661.97, an amount which was reimbursed to the Sanitary District by the packers.

For the Tannery industry, the investigations made between 1911 and 1919, gave a rough indication of the equivalent. However, the most detailed survey was made in the summer of 1921, when twenty tanning houses were inspected. For each house, the flow was gaged and analyzed, the work being done substantially in the same manner as for the Packinghouse survey. The determination of the biological oxygen demand and the flow from the houses showed a total oxygen requirement equivalent to 70,000 people, on a normal hides capacity rating. In addition, seven wool pulleries and three [fol. 369] wool scouring houses were examined.

For the Corn Products Refining Company, the investigations were made in December 1921, and January and February 1922, in connection with the testing station then operated on the Corn Products wastes. The flow was gaged and sampled throughout the twenty-four hours, analyses being made on twenty-four composites. The result-

ing oxygen demand showed that the population equivalent was 411,000 people, at that time when a grind of 64,500 bushels was being made. Since that time the grind has increased.

Q. What was the designed capacity of the Main Channel of the Sanitary District?

A. The Sanitary District Channel in the main section was designed upon the assumption that the runoff of the Chicago River would not exceed 10,000 cubic feet per second, and could therefore be diverted from the Lake by a channel having that hydraulic capacity.

Q. That is reversed at all times?

A. Reversed at all times, yes, sir.

Q. If the diversion from the Lake is limited to 4,167 cubic feet per second, what effect will this have upon the problem of protecting the water supply?

A. The likelihood of overflow into the lake is very much increased, [fol. 370] with a result that pollution of the water supply is likely to occur, which will be severe. This is due to the fact that the intercepting sewers as designed cannot be made large enough to carry more than twice the dry flow in 1950; hence overflows will come into service, at times of storm, spilling sewage into the branches of the Chicago River. Consequently, with any reversal of the flow, storm water and sewage mixed will fill the river and be swept into the Lake.

Q. What methods would be necessary to pursue, in order to protect the water supply, in the event of the reduction of diversion?

A. It does not seem safe to me to rely entirely upon chlorination of the water supply for protection, where a water would be exposed to sudden and so-called explosive pollution. In my experience, the only adequate and certain protection would be filtration, accompanied by chlorination, as a finishing process.

Q. What is the extent of the use of water for domestic purposes now, and what do you estimate it in the future?

A. I have prepared an estimate of the use of water at the present time in the city of Chicago, that is as of 1920; and also for 1945 and 1955. These estimates have been checked with those of the Water [fol. 371] Bureau of the City of Chicago, and are in substantial agreement.

Q. That is the pumpage practically, isn't it, Mr. Pearse?

A. Yes, sir, that is practically the pumping.

Q. That has nothing to do with the diversion from the lake by the Sanitary District?

A. It has nothing to do with that.

Mr. Adcock: I offer in evidence this table that the witness has just presented, as Exhibit 7 of this date.

(Table of water consumption for 1920, 1945 and 1955, offered in evidence, was marked Pearse Exhibit 7, April 25, 1923, and is hereto attached.)

Q. Have you made any estimate of the cost of the construction and operation of plants for filtering the water supply of Chicago?

A. I have made a rough estimate of the cost of filtration, basing the capacity of the plant on the maximum daily rate, and including in round figures the low lift pumping stations.

In 1945, the cost would be for construction approximately $90,000,000, or by 1955, a cost of $106,500,000. These costs are in [fol. 372] round figures, and undoubtedly would require some additional expansions to increase the figures in a detailed survey, because of the necessity of the connections to the intake tunnels and other incidental work, which at present it is difficult to estimate. I present them as an indication of figures based on the cost of works in the past and present, to show the magnitude of the filtration expenditure.

Q. You say "a rough estimate," what do you mean by that?

A. I mean an estimate that may be within 15 or 20 per cent, based on round figures, calculated per million gallons for plants of like nature. They are figures that perhaps are not accurate enough to predicate a bond issue upon for a public vote, but are accurate enough to indicate the magnitude of the expenditure for handling the filtration of a city of the size of Chicago. Such a plant would be the largest filtration plant of its kind in the world, and would necessitate special designs and lay-out, so that the figures necessarily at the present moment are not contractors' estimates of what the work could actually be built for, but they are what we call preliminary estimates which may be accurate within 15 or 20 per cent, [fol. 373] thereabouts.

Q. What would be the probable annual cost of maintenance and operation of such works?

A. I believe that in 1945, the cost of maintaining and operating such filter plants for the city would exceed three million dollars, and that by 1955, the cost would have probably reached $3,526,000, the additional cost being due to the additional service required for the population, and increased pumpage.

To these figures necessarily should be added interest charges and depreciation, to give the total annual costs. These costs cover labor, chemicals, supplies and general repairs necessary and incidental to the operation of such filtration plants.

Q. Based upon the project, the plan outlined by the ordinance of August 7, 1919, what populations would require treatment?

A. I have made a calculation based on the so-called "Colonel Judson plan,"—if I understand the question.

Q. Yes.

A. Which was designed to outline the program for the Sanitary District for the twenty-five years following 1920, to construct works which would reduce the load on the channel to one-half that exist-[fol. 374] ing in 1920. The figures are presented as follows:

For Conditions in 1920

By census, S. D. C. in 1920	2,986,000
Estimated Industrial Wastes	1,500,000
Total	4,486,000
One-half	2,243,000

Q. That is an equivalent population, human population?

A. Equivalent population expressed in the equivalent sewage from human beings.

Q. That is that represents, according to such estimates, half the waste passing from the southern terminus of the Main Channel of the Desplaines River?

A. Yes, sir. The figure of 2,243,000 is in round figures to the nearest thousand.

The equivalent population, under the Colonel Judson plan that would be required to reduce the sewage pollution to in 1945, outlined In 1945, the conditions are as follows:

For Conditions in 1945

Estimated S. D. C. in 1945	4,782,000
Estimated Industrial Wastes	2,000,000
Total	6,782,000
Deduct residual one half	2,243,000
Requiring treatment by	4,539,000

[fol. 375] 4,539,000 is the population which I understand would have to be provided for by treatment works, under this so-called Colonel Judson plan.

Q. That is during the period from 1920 to 1945?

A. Yes, sir.

Q. What flow of dilution water does this plan provide, or would this plan provide in 1945?

A. I have based the figures on the minimum legal dilution expressed in the Act of the Sanitary District, namely 3 1/3 cubic feet per second per thousand population, and on that base I find the population of 2,243,000 requires 7,500,000 cubic feet per second, in round figures, for dilution. From the sewers there may come a flow which we have assumed to be 346 gallons per capita per 24 hours for a population of 4,782,000 in 1945, which would give a flow of 2,482 cubic feet per second, making a total flow through the channel of diversion from the lake, and of water supply coming through the sewers of practically 10,000 second feet; a difference of only a few unit second feet, so that it rounds out to the 10,000 second feet.

Q. If by the year 1945 the flow were reduced to 4,167 second feet, on this basis, what population would that flow accom-odate, or equivalent population?

[fol. 376] A. On the assumed basis of the minimum legal dilution of 4,167 cubic feet per second, at 3½ cubic feet per second per thousand population, is equivalent to 1,250,000 people. In 1945, the total population equivalent, both human and industrial is estimated at 6,782,000. The difference, or 5,532,000 people would require treatment. In 1945, this means 993,000 more people than would be required under the Colonel Judson plan.

Mr. Fleming: The testimony now being presented, as I understand it, is presented merely for the enlightenment of the court in connection with the character of the decree he shall enter.

Mr. Adcock: Yes, and they are matters that were brought out in the argument of the motions; and are pursuant to the written motion presented.

Mr. Fleming: My objection specifically is this: I object to the reopening of the case on any of the issues; the elaboration of any of the testimony on any of the issues in the original case. In that case the record has been made, the testimony heard, and an informal opinion rendered by the trial court. And to all intents and purposes, disposition has been made of this case, and the only matter pending now is the question of the form of the decree which should [fol. 377] be entered.

It is my understanding it was Judge Carpenter's suggestion that there was no objection to taking testimony insofar as the presentation into this record of the ordinances of the Sanitary District was concerned, and the testimony, moreover, on the subject of the construction of these plants. My stipulation, in any event, was limited to those two propositions. I could not stipulate nor agree to any further testimony at this time; testimony introduced as to the merits of this case.

Mr. Adcock: I want to say in behalf of the defendant, there isn't any attempt to re-open any of the issues that were presented in the original case. This testimony is in connection with the motions that were made, the form of the decree to be presented, in order to give the court the facts upon which he may act in determining the decree that he shall enter, and it is only for that purpose.

Mr. Fleming: I reserve the right to present objections to this, and to strike this——

Mr. Adcock: Strike any portions you want to under the terms of the stipulation, anything that is objected to on the ground of mate- [fol. 378] riality, relevancy and competency; also under any other stipulation.

Mr. Fleming: That was the original stipulation.

Mr. Adcock: Yes.

Mr. Fleming: But this matter is something that is outside; the issues have been settled, the matters submitted to the court. This testimony of Mr. Pearse with respect to the back flow of the river, the flowing of the river into Lake Michigan in the event of reduction to 4,167, testimony of that character is something not within the authorization of the court, and certainly not within the stipulation between yourself and me.

Mr. Adcock: That we believe to be material in connection with the issues that we believe are now before the court, on the motions that were recently argued, and upon the question as to the decree that the court may enter; and it is for that purpose only we are offering the evidence. As far as I am concerned, I agree that the objections which counsel wishes to make may be presented to this testimony now, or at any time that he desires.

Whereupon an adjournment was taken to Thursday April 26th, two o'clock P. M.

[fol. 379] Thursday, April 26, 1923—two o'clock p. m.

Parties met pursuant to adjournment.
Present as before.

Langdon Pearse resumed the stand for further direct examination by Mr. Adcock and testified as follows:

Q. How long would it take, probably, to build these additional works for the 993,000 people?

A. I estimate not over ten years.

Q. According to your estimates, what would be the human population and the equivalent in industrial wastes?

A. The human population would amount to 5,500,000 in 1955, and the industrial wastes 2,200,000, making a total of 7,700,000.

Q. What population would require treatment then by 1955 on the reduction of flow to 4,167 second feet; also the increase over 1945?

A. The figures given previously may be developed as follows: The total population in 1955 we have estimated at 7,700,000; the total [fol. 380] population in 1945, at 6,782,000, making a difference of 918,000 population, as the growth in the ten years.

If you take the total in 1955, namely 7,700,000 and from this deduct the population equivalent to the 4,167 cubic feet per second, namely 1,250,000, you have as a difference as of 1955 a population of 6,450,000.

Under the Colonel Judson plan as mentioned before, the population requiring treatment in 1955 would be 5,457,000, the difference then between the two being 993,000 people.

Q. What is the cost of the artificial sewage treatment program, under the plan of the ordinance of August 7, 1919, which we will call the Colonel Judson plan for convenience? Have you made an estimate of that.

A. We have made an estimate of the cost. The sewage treatment program based on this plan was estimated in 1920 to require directly an expenditure for sewage treatment of $104,335,000, out of a total program of over 106,000,000. I say over $106,000,000 because in addition to the $104,000,000 would be the other items such as regulating works, bridges over the Main Channel, and dredging of the [fol. 381] Calumet River, which amount to $7,250,000. Of the total as estimated, over $9,490,000 has been spent or put under con-

tract to date, thus leaving a total of about $94,845,000 still to be expended.

Q. The amount of approximately $9,000,000 there which you have stated, has been expended since 1919 or 1920, has it, or been contracted for?

A. Has been either expended or contracted for since 1920.

Q. That is when you say "contracted for" that means under actual contract?

A. Yes.

Q. That is contracts let and in performance?

A. Yes.

Mr. Fleming:

Q. How much was that?

A. $9,490,000, that is under contract or completed, during the period from 1920 to date. The cost of each project is indicated in the exhibit, as well as the year.

Mr. Adcock:

Q. Indicated on an exhibit or tabulation, which you have prepared here?

A. Yes, sir.

Q. And which you hand me?

[fol. 382] A. Which I hand you, yes.

Q. You have made up these figures, or they have been made under your direction, have they?

A. These figures were made up under my direction, and represent the combined judgment of our office.

Mr. Adcock: The tabulation which you have handed me bears the legend, "The Sanitary District of Chicago estimated costs of sewage treatment projects and necessary construction work for period 1922-1845", and I will offer that in evidence as Pearse Exhibit 1 of this date.

(Blue print, estimated cost of sewage treatment projects and necessary construction work 1922-1945, offered in evidence, was marked Pearse Exhibit 1, April 26, 1923, and is hereto attached:)

Q. What progress does this schedule of progress call for or contemplate, both on new work and extension of existing works?

A. We based this schedule on the following assumptions as to the progress that might be made. I would make this explanation, however, that this general program was worked up in 1922, that is not 1923, and we estimated then that the North Side work would [fol. 383] be started in 1922. The plans were practically ready last fall for the first contract of that plant, but owing to the discussion with Evanston over the location of the site, the work has not actually been put under contract, but the program is outlined to start on the North Side plant in 1922, and completed by 1928.

Q. You say "discussion with Evanston," do you mean then that there were objectors as to the site? You have a site there now?

A. The District has acquired approximately 200 acres at Oakton Avenue and the North Shore Channel for the purpose of a site. This site was acquired about two years ago. Last year, when it was announced that we were prepared to start work on the plant, objections were raised by various Evanstonians, and only to-day a large delegation was in the office before a public hearing of the Trustees, protesting against the use of that site, and alleging possible damage to the property values in Evanston.

The Trustees have indicated as yet no decision in the matter, but have been investigating very seriously the entire question since last October. The change in the Board in December re-aligned some of the committees. We expect a decision shortly, and orders to pro-
[fol. 384] ceed in one way or another on actual construction.

Q. As I understand the proposition they bring up is that they want to annex about 2,500 acres to Evanston, is that correct?

A. The reason for the objection is that Evanston has expressed a desire to annex 2,500 acres west of the Channel, extending out towards the north branch of the Chicago River north of Oakton Avenue; and the claim is made that the location of this plant will injure the desirability of that locality for the best class of residential buildings.

I would add this, however, that on this north side project we have already built five miles of sewer from Sheridan Road south to Oakton Avenue, so that the northwest line of the incercepting sewer is completed and ready to hook into the pumping station. And we have completed preliminary plans for the work from the south, and have already started on the plans for re-modeling Lawrence Avenue, so that the sewage that now passes to the river through the Lawrence Avenue conduit from the Lincoln Park region will be diverted to our interceptor.

Q. The program of the Evanstonian objectors is that you should
[fol. 385] move this plant out several miles, at a cost of something like $5,000,000 for sewer, is that right?

A. Yes, sir. The suggestions of Evanston are that we can move the plant five miles or more to the West, which would increase the sewer cost of the project at least a million and a quarter a mile for about four miles anyway, as a minimum. That is five million dollars and this would probably add to the operating expenses for pumping the sewage approximtely $100,000 a year.

Q. And the land, the 2,500 acres, is worth about $1,000 an acre.

A. I have been informed that that land is worth about $1,000 an acre. Our Board paid $1,500 an acre for the site of the treatment plant.

Q. You haven't finished your answer to the previous question?

A. No, sir. In our schedule, we further assume that the Corn Products plant could be started in 1925, and completed in 1927. I purposely allowed three years there for legal conditions, to arrive at an agreement with the Corn Products, because in our experience with the packers, after we had outlined the engineering plans for do-
[fol. 386] ing the work, that overcame the engineering objections,

we have been approximately four years negotiating as to the legal difficulties; and negotiating to arrive at an agreement under which the work could be prosecuted.

For the Stock Yards project, we allowed for a start in 1925, and assumed it would be completed in 1932. In making this allowance, we assumed that legal negotiations would take at least two years: that the design of the sewers and works would be done by 1924, and the construction of the sewers, pumping station, screens, and the first unit of aeration tanks completed in 1926. After operating for one year, a year is allowed for the design and contract plans for the entire plant, and a year for necessary legal negotiations. The plant is assumed to go under construction in 1929, and to be completed in 1932.

I would explain this arrangement was made, because when Mr. W. B. Richardson, representing the packers, and myself representing the District brought in a report outlining the engineering method of proceeding, in 1917, we made a recommendation that the work be done by gradual steps, first to construct the sewer, pumping stations and screens for the entire works. Mr. Richardson [fol. 386½] differed with me and said we ought to have the screens only for one unit, that is about one thirtieth of the entire flow, and then we both agreed that the activated sludge plant recommended by both of us as to process should be built gradually, in order to demonstrate to the packers on a working scale of at least a million and a half gallons per day, the entire feasibility of the process.

Since that time, I have taken the position that the size of the plant to start might be markedly larger, as we know more of the process to-day, and have been operating a plant at Maywood for over eight months.

Q. You have a little different situation as to the sewage at the Stock Yards from the one you have with the human sewage in Maywood, don't you?

A. The sewage is much stronger at the Stock Yards, expressed in biological oxygen demand. The sewage in the Stock Yards will run from 500 to 1,000 parts per million, as against 125 to 150, not over 200 in Maywood.

The amount of suspended matter in the Stock Yards will run from 3,000 to 4,000 pounds of dry matter to the million gallons, [fol. 387] whereas at Maywood we have 1,000 pounds. In other words, there is three to four times as much solid to be handled.

Further, with the screens at the Stock Yards, we estimate we can take out about 1,000 pounds of dry material to the million gallons, whereas at Maywood we are only taking out 200 pounds a day for 3,000 gallons. That is 60 pounds of wet material with 80 per cent moisture, or 16 pounds of dry material to the million gallons.

The Stock Yards sewage is one of the strongest sewages in the United States produced on such a scale, and is full of fresh organic matter, blood, particles of meat, hay, straw, and undigested contents of cattle paunches, hogs and other animals.

Q. Has any practical, satisfactory method been developed for the

reduction and disposition of the sludge coming from these activated sludge plants?

A. I feel that a reasonable program of handling has been devised, namely to de-water the sludge, which in its original form contains about 99 per cent of water; reduce that to 80 per cent or less by filter process, with the addition of either an acid or a coagulen like sulphate of alumina, and then take the solids with less than 80 per [fol. 388] cent of moisture and dry them in a rotary heat drier. They will then be in a form containing ten per cent of moisture, capable of passing through an eight mesh sieve, and suitable for sale in the market as fertilizer. We have been offered by at least two responsible firms the amount of five dollars and ten dollars per ton f. o. b. cars for Chicago for such material, to be used in mixing fertilizer for the Southern market, or for truck farms either in the East or the Ohio Valley.

Q. That has just been recently worked out?

A. That has been worked out in the last two years. In addition, the city of Houston has been selling similar material for eight dollars a ton for use in the Cotton Belt in the South, prepared in much the way that I have indicated.

The City of Milwaukee is installing a plant now to handle the sludge in exactly this fashion.

Q. What other project have you there that you have considered, and what is the time of construction?

A. In order to build up a sufficient treatment to meet the requirements of the Colonel Judson program, or a more elaborate program, we have had to plan the construction of the so-called West Side Project, including the sewers, and a plant which, for the purposes [fol. 389] of this estimate, we have assumed would be a settling plant to remove all the solids which may settle in the Channel. The construction of this plant has been assumed to begin in 1932 and to be completed in 1940.

Further, for the South West Side, we have laid out a similar program for treatment, including intercepting sewers and a settling plant, the construction to start in 1935 and to be completed in 1945.

Besides the new work which I have mentioned, viz: The North Side, West Side and South West Projects, the extension of existing projects will require attention in the life of the program.

The Desplaines River sewage treatment works, which has been in operation since August 1st, 1922, will need extensions in 1924 to take care of the increased population.

The Calumet treatment works, which has been in operation since October 1922, will need an extension of the tanks, and we have assumed an addition of sprinkling filters to produce a higher grade effluent than we were supplying, in the year 1930.

[fol. 390] We have further allowed for the extension of the North Side treatment works, assuming that they were completed in 1928, in the year 1931.

Q. What population does this program cover?

A. As originally outlined the program covers an equivalent population of 4,251,000, taking the Imhoff tank treatment as the equiv-

alent of one-third complete treatment. This is within five per cent of the figure set for 1945, as outlined by the Colonel Judson plan. This method of handling was assumed by settling the sewage which was not given complete treatment, in order to retain all the settling solids.

I would explain that the reason for presenting the material in this shape is, we have to construct certain intercepting sewers to take out the sewage and carry it to certain designated points for treatment. Having done so, those sewers serve for a certain population, and we have taken the tributary populations and added them together in order to supply a project that would come approximately to the population set by the plan. In order to bring it exactly to the plan, we would have to provide a little additional treatment, as I remember, because I think the figure of 4,251,000 is a little lower than the [fol. 391] amount called for, which would of course increase the expense of the construction.

I did not endeavor to bring it out exactly by taking the per capita figures and equating them by slide rule, but have left them in this shape to show exactly the projects that would be developed, and what they would accomplish.

Q. What change of construction program would be required if the contemplated diversion were cut to 4,167 c. f. s. by 1945?

A. If the flow were cut to 4,167 c. f. s., it would be necessary, we believe, by 1945 that the West Side plant, instead of being constructed with settling tanks would be equipped for complete treatment, probably by activated sludge. We would still leave the South West plant as a settling plant. Such a program would provide in the year 1945 for the population equivalent of 5,328,000, which comes within four per cent of the figures set.

The same explanation would apply here as made in the previous answer, namely that in order to come out exactly to the population set by the population computations, sufficient additional treatment would have to be provided on one plant by sprinkling filters or other [fol. 392] means, to bring up the total, which can be done, but would increase the amounts of the estimates.

The additional construction cost necessitated by the cut in diversion would exceed $16,800,000 if carried out by 1945. I have my doubts whether this could be done at the rate of progress that is necessitated by the methods of administration in our work and the financing, judging by past experience.

I have therefore estimated that in order to finance the work, cover the legal requirements and the like, somewhat more time would be required than on the previous work, which has been taken to be a period of ten years. In the interval from 1945 to 1955, in which the extent of that cut would be made, working on our assumptions, there would have to be expended not only the sum of $16,800,000 as noted, but a further sum roughly estimated at $16,710,000, making a total of $33,510,000, to cover the growth in population, which would have to be treated, as well as the difference required on account of the lowered diversion.

In addition to these figures, in accordance with a former answer, the filtration of the water supply of the City of Chicago would be [fol. 393] required, so that as of the year 1955, there would be added $106,500,000 to the program requiring financing.

Q. That is the sewage treatment program you have outlined?

A. To the sewage treatment program, yes.

Q. Is the true cost of handling the additional population of 993,000 shown by your computation?

A. The true cost of the additional population is not shown by our method of computation outlined, because the method of assembling by districts indicates a comparative cost for handling the sewage with a reduced diversion, which is lower than it really is, if you take the per capita costs and multiply by the population. That comes in the method of assembling the projects and calculating the cost of intercepting sewers in this treatment.

Q. What do you estimate the per capita cost to be?

A. I have estimated the cost of the activated sludge plants with intercepting sewers as $25 per capita, with an annual cost of around $2.25 to $2.75 according to the method of handling the sludge. I am therefore conservative in saying the cost in round figures on [fol. 394] account of this cut in diversion would add to the sewage treatment program approximately $25,000,000 based on the actual per capita charges for construction, and $2,250,000 for annual costs.

Q. Would there be any effect upon the cities other than Chicago?

A. If the diversion was cut to 4,167 cubic feet per second, I believe that there will be ultimately a heavy burden placed upon the cities and industries located on the Illinois River, particularly in the metropolitan area around Peoria and Pekin. While in 1920 the census population was only 88,207 for the two cities, there was in addition a starch works at Pekin grinding about 25,000 bushels of corn a day, equivalent to 158,000 people, besides other Corn Products industries about which little data could be obtained.

This equivalent population, through growth of industry as well as of population, I have estimated might exceed half a million in 1930. With the continued growth up to 1945, during low water, treatment may become necessary, making an additional burden upon the inhabitants of the State of Illinois. In 1920, the urban population on the banks of the Illinois River from Joliet to the mouth totaled 200,472.

Q. What expenditures have been made by the Sanitary District [fol. 395] for sewage treatment since 1909, for construction purposes?

A. I have assembled these expenditures in a table showing the amount spent year by year, which I hand you; these expenditures being taken from the books of the District and tabled.

Q. This table is entitled "Expenditures for Sewage Treatment since 1909, for Construction Purposes." You have assembled this, have you, from the records of the Sanitary District?

A. I have assembled this from the records of the Sanitary District and had them checked by our own clerical force, so that they are reasonably accurate.

Mr. Adcock: I offer that table in evidence as Pearse Exhibit 2 of this date.

(Table of expenditures for sewage treatment since 1909 for construction purposes, offered in evidence, was marked Pearse Exhibit 2, April 26, 1923, and is hereto attached.)

Q. Since January 1st, 1919, you have expended $16,382,944, is that correct?

A. Yes, sir.

Q. That has been spent under your direction?

[fol. 396] A. This money was spent under my general direction, under the orders of the Chief Engineer who is in charge of the entire engineering department, and was spent in accordance with the plans and specifications drawn by my division of the engineering department.

Q. You made up a table showing the expenditures for sites?

A. I made up a table showing the expenditures for sites, a copy of which I hand you as an exhibit.

Mr. Adcock: I offer that table in evidence as Pearse Exhibit 3 of this date.

(Table of expenditures for sites for sewage treatment works up to 1921, offered in evidence, was marked Pearse Exhibit 3, April 26, 1923, and is attached hereto.)

Q. You made that up in the same way as the others, from the records of the District?

A. This table was made in the same way, from the records of the District, checking the amounts against the vouchers paid, and the dates against the orders of the Board printed in our proceedings.

Q. What expenditures have been made by the Sanitary District since 1909, for testing stations and experimental work?

[fol. 397] A. Since 1909, up to the end of 1922, there has been expended under my direction by our engineering and laboratory forces the sum of $97,842, for construction and equipment on sewage testing work.

In addition to this sum, we have spent in the maintenance and operation of the works, including the operating of our laboratories and the other expenses chargeable to the investigations, the sum of $563,815. This makes a total expenditure on our books for construction, equipment, maintenance and operation of $661,657.

Q. Why was it necessary to do this?

A. When I first came with the District in 1909, the art of sewage treatment was less understood on a large scale than now. There was a transition period in the art; the old septic tank was in disfavor, as originally installed at Columbus. Experiments were found to be necessary, and were devised by men of the standing of Mr. Rudolph Hering, and others who studied the problems of the District, and had been connected with it since its inception in 1889.

We found the sewages we had to meet were so varied in strength and behavior that tests were needed to define the most efficient

method of treatment. Tests were needed in order to find how much [fol. 398] sewage could be treated with a given area of plant; for instance in sprinkling filters, how many hours were required for the settling of the sewage in settling tanks.

We saw very clearly that the problem ahead of the District in 1909, was a gigantic one, involving the largest sewage treatment works in the world, and involving the necessity of producing a high grade effluent for a large part of the sewage of the District.

In addition, we had to confront not only the human problem but the industrial waste problem of enormous extent, and at that time no solution was known for its treatment. Neither was the amount of the waste known. The period required for preliminary investigation was indefinite, but we knew that we had to study the sewage, not alone as to methods of treatment, but also to improve the methods of analysis.

The method I have explained of determining the oxygen consumption was one of our changes in method which has enabled us to express population equivalents. Short time tests we knew were of little value. Our experience had shown that at least a test running over the four seasons of the year was required, because the [fol. 399] operation of a sewage plant is different in the winter from the summer; and usually at the end of the year we had found improvements or changes in the studies that led us to continue.

Aside from the tests, surveys were required of the District. Preliminary plans had to be made; sites had to be secured, and then legal obstacles had to be overcome.

Our lawyers finally determined that the Act had to be amended, which was done in the last session of the Legislature, over two years ago now, whereby we were given the explicit right and command to build sewage treatment works, whereas prior to that time, I was informed that our right to establish complete works was in doubt and open to contest.

Q. That is they were built as incidental to the works of diversion, and supplementary to them, under the original theory, is that correct?

A. Yes, the opinions, I think during Mr. Adcock's incumbency as attorney, and prior to that time, were that whatever we did was merely an incident, and there might be a doubt if we had to condemn a site as to whether our powers would be seriously questioned, because we were acting more or less under implied powers, instead of actual, explicit powers.

[fol. 400] Q. How about your population figures there, with reference to the effect on loading of the Canal?

A. I regard the population figures as presented as very fair. They are calculated from census figures, which are as close as we can actually get them. We have had the advantage of the actual enumeration districts of the census. In representing the actual loadings on the Main Channel, we believe they may prove low rather than high, because of the fact we have made no allowance in the figures for the floating population in Chicago, and in particular for the Loop

District. In 1920, this was estimated at 250,000 people. Of these 250,000, some are commuters from within the boundary of the district, but many undoubtedly come from the outside, according to our figures.

The hotels and clubs we think may house 100,000 people. The increase in floating population we have determined to be approximately 50,000 for every decade, so that we believe by 1945 that there is an effect from the floating population which might be between 375,000 and 475,000, for which we have made no allowance in these estimates.

We have also made no allowance for any factor of safety, to take [fol. 401] care of the variations due to the variations in industry, or to extremely hot weather, which you may get in the summer time, that would upset our allowance of the effect of the water taken from the Lake, or for other contingencies.

Neither have we allowed for any extension of the boundaries of the district, which I believe will undobutedly occur, as shown by our past experience. All these factors would tend to increase the expenditures for sewage treatment.

Q. And your cost figures, are they conservative?

A. I think the estimates of cost of construction are conservative. We based them on unit prices slightly lower than have prevailed in the last two years. The office experience in the Sanitary District during the last two years, and in fact since the beginning of the war, has indicated that the contractors that we have to deal with want more for doing the work than we as engineers generally estimate. I think in our experience in the last two years, if I am not mistaken in my recollection, we have in general received figures that are higher than the estimates we have made as engineers, along the lines indicated in my evidence.

I have further assumed that the general conditions of labor, and [fol. 402] of the material market, will continue. I have not attemped to estimate the possible changes that may occur in the stretch of twenty-five years.

Q. You have handed me a table here entitled "The Sanitary District of Chicago, expenditures for construction of sewage treatment works 1910-1922, showing the expenditures by years. You have made these figures from the records of the district, have you?

A. Yes, sir, I have had this table, which may be identified as Exhibit 4, prepared to show item by item the expenditures made from 1910 to 1922, on the different projects of the district applicable to sewage treatment. That is for intercepting sewers, pumping stations and sewage treatment works.

Mr. Adcock: I offer this table in evidence as Pearse Exhibit 4.

(Table of expenditures for construction of sewage treatment works 1910-1922 offered in evidence was marked Pearse Exhibit 4, April 26, 1923, and is hereto attached.)

[fol. 403] HENRY M. CHRISTIE, a witness called on behalf of the defendant, was first duly sworn by the Commissioner, and testified as follows:

Direct examination.

By Mr. Adcock:

Q. What is your full name?
A. Henry M. Christie.
Q. Where do you reside?
A. 4336 West 22nd Street, Chicago.
Q. Are you employed by the Sanitary District?
A. Yes, sir.
Q. How long have you been so employed?
A. With the exception of an interval in 1901-1902, and another interval in 1909-1910, since April 1892.
Q. What are your present duties with the Sanitary District?
A. Emergency work.
Q. Have you had any experience in accounting work?
A. Yes, sir.
Q. In the case of Duffy vs. Sanitary District, you did quite a lot of work, did you not, as accountant?
A. In June, on June 9, 1906, what was known as Waterpower Development Sections 1, 2 and 3 at Lockport were taken from the J. J. Duffy Company, and I was delegated by the Chief Engineer [fol. 404] to go down and take charge of the business end of the work, which continued the remainder of 1906 and all of 1907.
Q. Have you made any estimate of the present and future resources of the district, by way of bond issues and probable tax income as based upon the statute providing for the taxation by the trustees of the district, for levying taxes by the trustees of the district?
A. Yes, sir.
Q. Just state what you have done?
A. In March 1922, working with Mr. Raney, the present Assistant Chief Engineer, we compiled a table showing annually our expectations in income, consolidated with certain estimates of the Sanitary District Engineers as to a construction program; and brought that table down from 1922 to 1945 inclusive.
Q. Have you got that table here?
A. Yes (producing same).
Q. Now, will you take this table that you have just handed me, entitled "The Sanitary District of Chicago, composite statement estimating resources and liabilities under 1945 construction program": there are various columns there, varous headings and figures, will you state what those different columns mean and how they were gotten up.
[fol. 405] A. Column No. 1 shows the years.

Column No. 2 shows the population increment as based on the rates of increase shown by the last decennial period.

Q. Shown by Mr. Pearse?
A. Shown by Mr. Pearse and taken from the same basis.

Column No. 3 shows the estimated valuation, assessed valuation as taken from information obtained from the Assessor's Office of Cook County, the increases being based on past experience.

Q. So that you start out with an assessed valuation of nearly two billion dollars in 1921, and you have an assessed valuation in 1945 of $3,300,000,000?
A. Yes, sir. Column No. 4 shows the assessed valuation per capita.

Column No. 5 shows the future tax rate as taken uniformly at .40 of 1 per cent, this being assumed as the limit which the Sanitary District is likely to realize under the present conditions.

Q. You show 1921 as .36.
A. $0.36, that is all we may obtain that year. The taxes for 1922 are spread on 40 cents.
Q. Actual.
A. Actual, spread at 40 cents.
[fol. 406] Q. The same as for 1923. That has not been determined.
A. That assume we can do as well as 40 cents.
Q. That has not been determined yet?
A. Column No. 6 shows the taxes for any one year based on the assessed valuation of the preceding year. That is the taxes spread for 1923 will not be collected until 1924, so we show in that column the actual collection of taxes in that year.
Q. And that is less a certain amount for loss, on account of delinquents and costs of collection?
A. Yes. I would like to explain, in that 40 cents we figure a loss of at least ten per cent. That was Mr. Ramey's and our judgment at that time. I read in the paper the other day about a much greater loss this year, and I verified that by calling up Mr. Jacob Lindheimer, the Assistant Treasurer of Cook County in charge of collections, to-day, and he informed me that the loss this year would be fully 12 per cent; that delinquents this year amounted to $18,000,000 in all the public bodies in this county, so that the ten per cent in our judgment was not excessive at that time.
I would like to state too, in clarifying this: This statement was made in March 1922, and we estimated that the assessed valuation [fol. 407] would be $1,870,000,000. When we got our returns, we found that there was a reduction of the actual valuation for the year 1922 to $1,784,391,952.
Q. Now, you have column 7, bond issues.
A. Column 7, future bond issues, started in the year 1922 to provide the revenue necessary for the heavy construction program.
Column No. 8 shows the total gross revenues, and is the sum of the figures in columns 6 and 7, being the combined sum of the revenues derived from taxes and from sale of bonds.

Column No. 9 shows the amounts required each year to liquidate the present outstanding bonds. These are for old bonds that have been issued for prior work.

Column No. 10 shows the amounts required each year to pay the interest on the present outstanding bonds.

Column No. 11 shows the amounts required each year to redeem future bond issues, except for one issue, $3,000,000, in 1921. The bonds are figured for redemption at the rate of 5 per cent per year.

[fol. 408] Column No. 12 shows the interest on outstanding bonds. The future issues are computed at the rate of 4½ per cent per annum.

Column No. 13, shows the estimated cost of administration, and the ordinary expenses of maintenance and operation of the work of the Sanitary District, based on the experience of recent years.

Q. And also, as you get along down further, you take into consideration the increase due to the additional works.

A. The cost of increase, to provide for the operation of the different plants, yes, sir; to take care of the Desplaines plant going into commission in 1923, the Calumet in 1923, the Southwest and so on.

Q. And Column 14 is the total?

A. Total expenditures.

Q. Column 15 is the net revenue?

A. The approximate net revenue available for new constructions.

Mr. Adcock: I offer this table in evidence as Christie Exhibit 1 of this date.

(Table entitled "Composite statement estimating resources and liabilities under 1945 construction program," offered in evidence, was marked Christie Exhibit 1, April 26, 1923, and is hereto attached).

[fol. 409] Q. Have you made up a table showing the movement of iron ore during the year 1920 in reference to harbors, and the net tons moved, and if you have, state how you made that table up?

A. I have. I have a table showing the movement of iron ore during 1920, compiled from Part 2 of Chief of Engineers U. S. Army Report for the Fiscal Year ending June 30, 1921.

Q. And that table is made up merely from figures you have taken from that report, is that correct?

A. Merely a compilation of the figures taken from that report.

Mr. Adcock: I offer this in evidence as Christie Exhibit 2 of this date.

(Table showing movement of iron ore during 1920 offered in evidence, was marked Christie Exhibit 2, April 26, 1923, and is attached hereto.)

Q. Have you made up a table showing comparison of depths in certain channels and harbors at sundry elevations of the waters of Lakes Michigan, Huron, Erie and Superior?

A. Yes.

Q. And also showing the project depths under acts of Congress?

[fol. 410] A. Yes, sir.

Q. How did you do that?

A. This is a comparison of depths in certain channels and harbors at sundry elevations of the waters of Lakes Michigan, Huron, Erie and Superior, compiled from Bulletin No. 31, "Survey of Northern and Northwestern Lakes" issued by the U. S. Lake Survey office, Detroit Michigan, April 1922, and water level records furnished by the same authority.

Mr. Adcock: I offer this table in evidence as Christie Exhibit 3.

(Table of Comparison of Depths in certain channels and harbors at sundry elevations, offered in evidence was marked Christie Exhibit 3, April 26, 1923, and is hereto attached.)

Q. Have you made up a table showing a summary of statement of resources and expenditures of the Sanitary District of Chicago under 1922-1945 construction program?

A. I have.

Q. And that is taken from the figures you have presented, and [fol. 411] also from figures Mr. Pearse has presented, is that correct?

A. Yes, sir.

Mr. Adcock: I offer this statement in evidence as Christie Exhibit 4.

(Table summary of statement of resources and expenditures of the Sanitary District of Chicago, under 1922-1945 construction program, offered in evidence, was marked Christie Exhibit 4, April 26, 1923, and is hereto attached.)

Adjourned subject to notice.

[fol. 412] PEARSE EXHIBIT 1

April 25/23

"An ordinance of the Board of Trustees of the Sanitary District of Chicago laying out and adopting a program for the construction and operation of works for the purification of or the removal of solids and organic and inorganic matter from sewage, trade waste, offall and other organic and inorganic matter so that within the period of the next twenty-five years not more than fifty per cent of the amount of said sewage and waste that is now passing into the Desplaines River from the main channel of the Sanitary District will at the end of such period find its way into said river. Such works are to supplement those constructed or in process of construction for the diversion of sewage and drainage arising within the limits of the Sanitary District of Chicago.

Whereas, the Sanitary District of Chicago was organized and now [fol. 413] exists under an Act of the General Assembly passed on

May 29, 1889, in force July 1, 1889, entitled, "An Act to Create Sanitary Districts and to Remove Obstructions in the Illinois and Desplaines Rivers," and Acts amendatory thereof or supplementary thereto; and,

Whereas, The said Act of the General Assembly provided for the construction and operation of the Main Channel of the Sanitary District, including adjuncts and additions thereto whereby the sewage and drainage of the City of Chicago and its environs should be diverted from Lake Michigan to the Desplaines river, together with a certain amount of water from Lake Michigan fixed acording to the population of the District as it might exist when such Main Channel should be constructed and as the population might thereafter increase, to-wit: Twenty thousand cubic feet of water per minute for each one hundred thousand of the population; and the Board of Trustees of The Sanitary District of Chicago is directed by said Act of the General Assembly to operate said works specified with such diversion of water; and,

Whereas, Said Act of the General Assembly was passed and the works provided therein to be constructed were built in order to re- [fol. 414] lieve the people of Chicago and environs of a serious menace to their health and lives arising by virtue of the pollution of Lake Michigan, the only water supply of Chicago by sewage passing into same by way of the Chicago and Calumet rivers and by way of sewers debauching directly into the lake at various points along Chicago's water front; and the said works were intended also to relieve the Desplaines and Illinois rivers of a serious condition of pollution due to a certain amount sewage and wastes of Chicago and environs passing into said river through the Illinois and Michigan Canal; and,

Whereas, The death rate per year from typhoid fever prior to the operation of the Main Channel of the Sanitary District at times equalled one hundred ninety per one hundred thousand of the population of Chicago, and its environs, which required the immediate construction and operation of works to relieve such condition; and,

Whereas, Immediately after the passage of said Act of the General Assembly of May 29, 1889, the Sanitary District was organized and thereafter commenced the construction of the Main Channel of [fol. 415] the Sanitary District, extending from Robey street and the West Fork of the South Branch of the Chicago river to the Desplaines river near Lockport, Illinois, a distance of thirty-two miles; and the work of constructing said Main Channel was carried forward with due speed until January 17, 1900, when the said Main Channel was placed in operation pursuant to the permit of the Governor of Illinois, in accordance with said Act, and the permit and consent of the Secretary of War of the United States; and the said Main Channel of the Sanitary District cost the people of Chicago and its environs many million dollars; and there was required for such construction the use of all the money that could be raised by the Sanitary District from taxation and by the issuance of bonds; and,

Whereas, The Sanitary District was compelled to construct and place in operation many adjuncts and addition to the Main Channel of the Sanitary District in order that the said Main Channel might accomplish the purpose for which it was constructed and there would thereby be constructed and placed in operation a complete and comprehensive system for a diversion of the sewage and drainage arising within the limits of the Sanitary District from Lake Michigan to the Desplaines river; and such works included the intercepting sewers and pumping stations on the North Shore and South [fol. 416] Shore of Chicago, the Calumet-Sag Channel, with its intercepting sewers, the enlargement of the flowage channel of the South Branch of the Chicago river and the West Fork of said South Branch, and the replacing of many old center-pier bridges with bascule bridges of modern type, and they included also many other works of similar character; and the construction of such works has largely engaged the resources of the Sanitary District, and

Whereas, the Works so constructed and placed in operation have caused a decrease in the death rate from typhoid fever per year in the City of Chicago and environs from an average rate of over seventy-five per one hundred thousand of the population for the ten years immediately preceding the opening of the drainage channel, so that now the death rate from typhoid fever is less than one-half of one per one hundred thousand of population; and,

Whereas, The Board of Trustees of the Sanitary District has recognized that by reason of various conditions existing, such as trade wastes and other materials passing into its channels and the inability to obtain at all points the necessary amount of water to dilute the sewage, thus causing local nuisances, that works should be constructed [fol. 417] and operated to remove a material portion of organic and inorganic matter from human sewage, and also to remove and eliminate a material portion of trade wastes and other materials so that the amount of organic and inorganic matter in sewage and the amount of trade wastes and other materials passing through the Main Channel of the Sanitary District into the Desplaines river would be materially diminished; and The Sanitary District of Chicago has for such purposes carried on experiments and investigations to ascertain the best method to accomplish such results; and it has constructed at Morton Grove, Illinois, an Imhoff tank for the removal of a certain portion of the solids from the sewage of the Town of Morton Grove, and is constructing in connection with such Imhoff tank a sprinkling filter to further purify the sewage of said town; and the Sanitary District is constructing an activated sludge plant with necessary intercepting sewers for the collection and purification of the sewage of the Towns of Riverside, Maywood, River Forest and others, the sewage of which towns is now passing into the Desplaines river; and the Sanitary District has authorized the condemnation of one hundred acres of land near the Calumet sewage [fol. 418] pumping station at 125th Street and Michigan avenue, Chicago upon which site there is to be constructed an artificial sewage disposal plant for the removal of organic and inorganic matter from human sewage and wastes that may pass into the Calumet in-

tercepting sewer; and the Sanitary District of Chicago has, in the Stock Yards District, to take care of the trade wastes of Packingtown, acquired a site for purification works to be constructed thereon to remove trade wastes and organic and inorganic matters from human sewage now finding their way from that locality to the Main Channel of the Sanitary District; and the South Park Improvement Project provides for the setting aside of sufficient land for the construction of purification works for the sewage and wastes collected at 39th Street and Lake Michigan by the intercepting sewers converging at that point, which intercepting sewers serve a population of approximately five hundred thousand people, and,

Whereas, The Chief Engineer of The Sanitary District of Chicago has made investigation of the amount of trade wastes and other wastes requiring pure water to oxidize same, now being discharged through the Main Channel of the Sanitary District into the Desplaines river, [fol. 419] and the Chief Engineer has found and the Board of Trustees of the Sanitary District believes that the amount of such wastes is approximately equal, if it does not exceed, the amount of human sewage now passing into said Main Channel and through same to the Desplaines river; and that there is required to oxidize said wastes and render same innocuous and nonputrescible, as much or more water from Lake Michigan than is required to oxidize and render innocuous and nonputrescible the human sewage of the present population within the territorial limits of The Sanitary District of Chicago; and by reason of such wastes passing into said channe land thereby into the Desplaines river, the works of the Sanitary District do not fully accomplish the purpose designed and nuisances are created at various places, which nuisances should be abated; and,

Whereas, It is the recommendation of the Chief Engineer of the Sanitary District that works should be constructed and operated to supplement the diversion works of the Sanitary District constructed or in process of construction whereby the amount of human sewage and the amount of trade wastes and other material should be continuously diminished from year to year so that at the end of a period [fol. 420] of twenty-five years at least only one-half of the amount of sewage, including all wastes that is now passing into the Desplaines river from the Main Channel of the Sanitary District shall enter same by way of said Main Channel; and the Board of Trustees of the Sanitary District believes that within the period of four years works of such character can be constructed and placed in operation to materially diminish the amount of such sewage and wastes passing into the said Desplaines river, as aforesaid; now, therefore be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. To supplement the works of The Sanitary District of Chicago now constructed or in the process of construction for the diversion of sewage or drainage, and to aid said works in better accomplishing the purpose for which they were constructed, the Sanitary District does hereby lay out and adopt a program for the construction and operation of works for the purification of sewage or the

removal of organic or inorganic matter from human sewage and the removal of trade wastes and other wastes and for the carrying on of such work at such a rate as continuously after the lapse of four [fol. 421] years to diminish the amount of sewage including all wastes passing into the Desplaines river by way of the Main Channel of The Sanitary District of Chicago, so that within the period of twenty-five years such purification works shall be constructed and in operation, that the amount of such raw sewage and wastes so passing into said Desplaines River shall be at least fifty per cent less than that passing now.

Sec. 2. The Chief Engineer and the Attorney of the Sanitary District are hereby directed to take such steps as may be necessary to carry forward the foregoing program, and the Chief Engineer is directed to report to such officers of the United States and the State of Illinois as may be interested, the progress made from time to time in carrying out said program.

Sec. 3. The foregoing preamble to this ordinance is hereby adopted and made a part of same.

Sec. 4. This ordinance shall be in full force and effect from and after its passage and adoption.

[fol. 422] STATE OF ILLINOIS,
County of Cook,
The Sanitary District of Chicago, ss:

I, William W. Smyth, Clerk of the Sanitary District of Chicago and keeper of its official records and seal, do hereby certify that the attached and foregoing is a true and correct copy of an ordinance of The Sanitary District of Chicago, entitled: "An Ordinance of the Board of Trustees of The Sanitary District of Chicago Laying Out and Adopting a Program for the Construction and Operation of Works for the Purification of or the Removal of Solids and Organic and Inorganic Matter from Sewage, Trade Waste, Offall and Other Organic and Inorganic Matter so That within the Period of the Next Twenty-Five Years Not More Than Fifty Per Cent of the Amount of Said Sewage and Waste That Is Now Passing into the Desplaines River from the Main Channel of the Sanitary District will at the End of Such Period Find Its Way Into said River. Such Works are to Supplement Those Constructed or in Process of Con- [fol. 423] struction for the Diversion of Sewage and Drainage Arising Within the Limits of The Sanitary District of Chicago," which said ordinance was passed by the Board of Trustees of The Sanitary District of Chicago at a regular meeting held on Thursday, August 7, 1919, and is now in full force and effect.

In witness whereof, I have hereunto set my hand and affixed the seal of The Sanitary District of Chcago this 27th day of May, A. D. 1922.

(Signed) Wm. W. Smyth, Clerk of the Sanitary District of Chicago. (Seal.)

[fol. 424] PEARSE EXHIBIT 2

April 25/23

An Ordinance of the Board of Trustees of the Sanitary District of Chicago offering and agreeing to defray the expense of the construction of works in one or more of the outlets of the Great Lakes to compensate for any diminishing levels of the Great Lakes and connecting waters due to the diversion of 10,000 cubic feet of water per second from Lake Michigan by the Sanitary District of Chicago and authorizing the attorneys of the Sanitary District in the suits pertaining to said diversion now pending in the District Court of the United States for the Northern District of Illinois, Eastern Division, to make and present such offer and agreement in open court.

Whereas, There are now pending in the District Court of the United States, for the Northern District of Illinois, Eastern Division, two suits in equity instituted by the United States against the Sanitary District concerning the withdrawal of water from Lake Michigan by The Sanitary District of Chicago. The first suit was [fol. 425] instituted in the year 1908 and pertains particularly to the construction and operation and withdrawal of water from the operation of the Calumet Sag Channel, an adjunct of the main channel of The Sanitary District of Chicago. The second suit was instituted in the year 1913 and seeks to enjoin the Sanitary District from withdrawing from Lake Michigan, through its various channels, including the Calumet-Sag Channel, then and now under construction, more than 4,167 cubic feet of water per second. The said suits have been tried together and submitted together upon briefs; and,

Whereas, The Honorable Kenesaw M. Landis, one of the Judges of said District Court of the United States, for the Northern District of Illinois, Eastern Division, before whom said cases have been pending, did recently render an opinion or direction for the entry of a decree in said cases, in substance, to enjoin the Sanitary District of Chicago, defendant in said cases, from withdrawing from Lake Michigan more than 4,167 cubic feet of water per second; and,

Whereas, Various reports have been submitted pursuant to acts of The Congress of the United States by the Engineer Corps of the [fol. 426] U. S. A. finding that the claim of injury to navigation arising from the lowering of lake levels be-ause of the diversion from Lake Michigan of water at Chicago to the extent of 10,000 cubic feet of water per second, may be compensated for by the construction of fixed weirs or works of similar character, or by the construction and operation of movable dams in the St. Clair, Niagara and St. Lawrence Rivers, or one or all of them, and that the expense of constructing said fixed weirs in the St. Clair and Niagara Rivers would, at the time the report was made, not exceed $475,000; and it was recommended that if The Sanitary District of Chicago should defray the expense of constructing such works, then they should be

maintained by and at the expense of the United States; and, if such works were constructed and placed in operation, thereby the ground of the United States for securing the injunction herein would be removed; and,

Whereas, It is the opinion of the Board of Trustees that if the Sanitary District is enjoined from taking more than 4,167 cubic feet of water per second from Lake Michigan for sanitary purposes, it will be necessary to expend, in the construction of works to arti- [fol. 427] ficially purify sewage, supplement and aid the works diverting 4,167 cubic feet of water upwards of $150,000,000, and the operation and maintenance of the same will exceed upwards of $5,000,000 per annum; and it is, further, the belief of the Board of Trustees of The Sanitary District of Chicago that it is doubtful whether such works, with said limited withdrawal of 4,167 cubic second feet of water will provide for the people of The Sanitary District of Chicago which includes the population of Chicago and its environs, a safe drinking water supply, for the reason that it would be impossible, with said limited withdrawal, to keep the Chicago River at all times reversed so that it would not flow into Lake Michigan, carrying with it a large amount of sewage and drainage, and it is doubtful whether such purification works would accomplish practical results.

Now, therefore, be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. The Sanitary District of Chicago does hereby offer and agree to defray the expense, and pay to the United States Government the cost of constructing and maintaining works to be installed [fol. 428] at the outlet or outlets of any of the Great Lakes to compensate for any diminishing levels of the Great Lakes and connecting waters, due to a diversion or withdrawal from Lake Michigan of 10,000 cubic feet of water per second by The Sanitary District of Chicago through its various channels and diversion works in the event The Sanitary District is not enjoined from diverting from Lake Michigan less than 10,000 cubic seconds feet of water.

Section 2. The said offer and agreement contained in Section 1 hereof is intended to embrace and cover not only the expense of constructing and maintaining fixed weirs or dams described in the report entitled "Final Report of Waterway from Lockport to the Mouth of the Illinois River," House of Representatives Document, No. 762, Sixty-third Congress, Second Session, but also any other works of similar character that may be planned or provided for by the Congress of the United States or by competent Governmental authority or works known as "regulating works," consisting of movable dams or dams that may be moved from time to time, that may be planned or provided for by the Congress or other competent authority, such works having for their purpose compensation for any diminishing levels of the Great Lakes or connecting waters due [fol. 429] to a diversion at Chicago of 10,000 cubic second feet of water, and the said The Sanitary District of Chicago offers and agrees

to pay to the United States the expense of constructing and maintaining such works whenever the United States shall provide for such construction and make request for the payment of the amount of money necessary to construct and maintain the same.

Section 3. The attorneys for The Sanitary District of Chicago, in said two suits above described, wherein the United States is complainant and The Sanitary District of Chicago is defendant, on behalf of The Sanitary District of Chicago, are hereby authorized, empowered and directed to present and make said offer in open court in said causes, or in any other manner that the said attorneys may deem proper.

Section 4. The preambles to this Ordinance are hereby made a part of same and this Ordinance shall take effect and be in force from and after its passage.

[fol. 430] STATE OF ILLINOIS,
County of Cook,
The Sanitary District of Chicago, ss:

I, William W. Smyth, Clerk of The Sanitary District of Chicago and keeper of its official records and seal, do hereby certify that the attached and foregoing is a true and correct copy of an ordinance of The Sanitary District of Chicago, entitled: "An Ordinance of the Board of Trustees of the Sanitary District of Chicago Offering and Agreeing to Defray the Expense of the Construction of Works in One or More of the Outlets of the Great Lakes to compensate for Any Diminishing Levels of the Great Lakes and Connecting Waters Due to the Diversion of 10,000 cubic feet of Water per Second from Lake Michigan by the Sanitary District of Chicago, and Authorizing the Attorneys of the Sanitary District in the Suits Pertaining to Said Diversion Now Pending in the District Court of the United States, for the Northern District of Illinois, Eastern Division, to Make and [fol. 431] Present Such Offer and Agreement in Open Court," which said ordinance was passed by the Board of Trustees of The Sanitary District of Chicago at a regular meeting held on Thursday, July 8, 1920, and was duly approved by the President of said Board of Trustees and is now in full force and effect.

In witness whereof, I have hereunto set my hand and affixed the seal of The Sanitary District of Chicago this 27th day of May, A. D. 1922.

(Signed) Wm. W. Smyth, Clerk of the Sanitary District of Chicago. (Seal.)

[fol. 432] PEARSE EXHIBIT 3

Chi. R., 140

May 24, 1921.

The Division Engineer; the Chief Engineers, U. S. Army, Washington, D. C.:

Cooperation with the Trustees of the Sanitary District of Chicago in Making a Study of Sewage Purification

1. Referring to the letter of the Chief of Engineers dated March 25, 1920 (E. D. 28918), instructing me to cooperate with the Trustees of the Sanitary District of Chicago in making a study of sewage purification, I desire to submit the following report of progress:

2. The history of the controversy between the United States and the Sanitary District may be briefly reviewed as follows:

Under a permit issued by the Secretary of War on December 5, 1901, the Sanitary District was authorized to divert through the drainage canal a maximum of 4,167 second feet of water from Lake Michigan for sanitary purposes. Since the permit was granted the Board of Trustees of the Sanitary District has made repeated applications for permission to increase the flow, which requests have [fol. 433] consistently been denied by the Secretary of War on the grounds that the permit already issued is of a temporary nature only and that congressional authority is necessary for any permanent diversion. In 1907 the Board of Trustees made application for authority to construct the Calumet-Sag Channel to connect the Calumet River with the main Drainage Canal, and to draw through it 4,000 second feet in addition to the 4,167 second feet previously authorized for the Chicago River. This application was denied, and the Board of Trustees thereupon declared its intention of proce-ding with the proposed work and withdrawing from Lake Michigan the additional 4,000 second feet without the sanction of the Secretary of War, unless prevented by injunction proceedings.

3. A suit was then instituted in March, 1908, by the Attorney General of the United States to restrain the Sanitary District from reversing the flow of the Calumet River and from withdrawing water from Lake Michigan in any other manner and in any greater quantity than that authorized by the Secretary of War.

4. Being thus stopped by court action from proceedings with its Calumet program, the Board of Trustees in 1910 applied for authority [fol. 434] to construct the Calumet-Sag Channel so as to carry the present flow through the two drainage canals instead of only one. In response to this application the Department on June 30, 1910, modified the existing authority so as to allow the previously authorized flow of 4,167 second feet to reach the main Drainage Canal through the Calumet-Sag Channel as well as through the Chicago River, provided, however, that the total amount withdrawn through

the two outlets should not exceed the 4,167 second feet already authorized to be withdrawn through the Chicago River alone.

5. However, the Board of Trustees was not satisfied with this limitation, and in 1912 made application for authority to withdraw through the two rivers, the Chicago and Calumet, a total of 10,000 second feet. After a public hearing this application was denied by the Secretary of War on January 8, 1913. As the Board refused to accept this decision, the attorney General filed another bill in October, 1913. This suit was combined with the one filed in 1908, but on account of the war and other reasons no decision was rendered by the court until June 19, 1920. On that date Judge Landis rendered an "oral opinion" in which he held that the 8,500 second [fol. 435] feet, more or less, which the Sanitary District was now diverting from Lake Michigan, had resulted in a lowering of the lake levels, and an impairment of the navigable capacity of all of the great lakes except Lake Superior; and that said diversion was not necessary "for the salvation of this community." He directed the attorneys for the two sides to get together and prepare for his signature an order sustaining the contentions of the plaintiff, to be effective 60 days after the meeting of the Supreme Court in October.

6. Instead of that, Judge Landis, in August, 1920, in the presence of the District Attorney and myself, heard the Sanitary District Attorney, Mr. Adcock, argue that the Judge should modify his oral opinion so as to allow a total flow of 10,000 second feet. As the arguments were not finished that day the hearing was adjourned to be concluded at his summer home at Trout Lake, Mich., on some day which was to be arranged later. On account of the sickness of the Judge's brother the adjourned meeting, which had been set for the latter part of August, was again postponed and has not been taken up since.

7. Ignoring all questions except that of the proper reduction and [fol. 436] disposal of Chicago sewage, by the existing method, it is apparent, from many considerations that an excessive amount of water from Lake Michigan is not being used. Contamination of the Illinois River is proceeding rapidly down stream toward Peoria; parts of the Chicago River and its branches show a state of contamination which is all too apparent to the eye and to the nose. It is easy to believe that if, under present conditions of sewage disposal, the amount of water from Lake Michigan is suddenly curtailed, the health of Chicago might be threatened. It is apparent therefore, that if the amount of water diverted from Lake Michigan is not to increase proportionately with the increase of population in Chicago and if health conditions in Chicago are to remain normal, there must be treatment of Chicago sewage. In 1919, with these facts in mind I took up with the Trustees of the Sanitary District the question of adopting an effective program for sewage disposal. As a result, a program was adopted on August 7, 1919, which contemplated that during the following four years there should be accomplished such work of land acquisition, planning, financing and actual con-

struction as would result in a continuous reduction thereafter of the raw sewage entering the drainage canal. The program further pro-
[fol. 437] vided that by the expiration of twenty-five years from the date of the program the work of purification shall have been so far advanced that the amount of raw sewage entering the Drainage Canal shall equal not more than one-half of that entering now, and this reduction must occur notwithstanding the fact that at the expiration of twenty-five years the amount of raw sewage produced in the district may be almost double that now originating there. Thus by the end of the twenty-five years period the Sanitary District might be required to treat some 50% more raw sewage than that now enters the Drainage Canal. The cost of carrying out this program was roughly estimated at $140,000,000.

8. The Sanitary District has had studies made by Mr. Francis C. Shenehon, a competent hydraulic engineer, for regulating and compensating works in the Niagara River and at the Galops Rapids in the St. Lawrence below the lower end of Lake Ontario. Mr. Shenehon has prepared preliminary plans and estimates for the works above mentioned. He estimates that regulating works in the Niagara River would cost approximately $1,224,000, and those at the Galops Rapids approximately $1,000,000. It is understood that the Sani-
[fol. 438] tary District, if the engineering propositions of Mr. Shenehon are approved by the United States, proposes to turn over to the latter the amount required for the construction of the works above described, the maintenance and operation of the same to be at the expense of the United States. These works, it may be said, contemplate a diversion of 10,000 cubic feet per second from Lake Michigan to the Drainage Canal. Digests of these two projects as prepared for me by Mr. Shenehon at my request are as follows:

Digest of Niagara Regulation Project

The Niagara River Regulation contemplates slack-water, vessel-draft betterments in Lake Erie, the Detroit River, Lake St. Clair and St. Clair River, Lakes Michigan and Huron and St. Mary's River to the locks at Sault Ste Marie.

The loss of draft due to a diversion of 10,000 second feet at Chicago is about 5½ inches. In a low water period such as the ten years 1893-1902, the regulation proposed will add over 14 inches to the depth of Lake Erie and Lower Detroit River; over 10 inches to Lake St. Clair, the Upper Detroit River and the Lower St. Clair
[fol. 439] River, with proportionate increase in St. Marys River. In a decade of more plentiful supply, the average betterment is less, because no increase in Lake stage is practicable at flood height. The regulation will compensate for lowerings due to all anticipated diversions at Chicago, in the Welland and Erie Canals and in the Niagara River for power purposes, and the regulation is accomplished without danger of riparian damage from flood stages.

The excess flow of May to August inclusive is saved to hol- up Lake Erie level during the season of navigation. The Niagara River

runs free from January to March inclusive, to avoid flood stages, to give unimpeded passage for ice and to add water for power purposes during the season of ice complications. Water power is the beneficiary of the larger winter flow, which averages 17,000 second feet in January and February, more than off-setting a diversion of 10,000 second feet at Chicago.

During the summer season about 30,000 second feet in addition to the controlled flow would be released during part of each day to furnish mill-pond water for power uses, so that the full natural river flow may pass over the cataracts to preserve scenic grandeur. Regu- [fol. 440] lation of the Niagara has been delayed by the fear of the people of Buffalo that regulating works would cause ice jams and hold up the vast ice fields which cover the east end of Lake Erie. This objection is met by placing removable vessel-type gates, which are removed in January and replaced in May.

The site chosen for works is at the head of the Niagara River, opposite the old water-works at Buffalo. The River is 1,800 feet wide here with bed limestone bottom. The river channel is divided into two sluice-ways by a submerged concrete wall, three-quarters of a mile long and parallel with the current. This carries a shutter dam to complete the partition and the shutters knock down during the winter. Four gates, each equipped with twelve large butterfly valves, close off the American Sluiceway. These gates rest and swing on massive concrete emplacements rising about two feet above the rock bottom. Special devices make the placing and removing of these gates easy. As each inch of added draft in Lake Erie is estimated as having a yearly value, of half a million dollars, the average increase of 13 inches is significant. The far reaching bene- [fol. 441] fits, from Buffalo to Sault Ste. Marie, without works or wiers in the Detroit or St. Clair Rivers, point this out as a project of great concern. The Niagara and St. Lawrence regulations work haul-in-hand.

Digest of St. Lawrence Regulation Project

The St. Laurence River Regulation contemplates higher surface levels for Lake Ontario in years when the lake is naturally low, and the avoidance of high stages which might cause riparian damage. This depends on the simple principles of slack-water betterment, utilizing movable regulating gates, which when open leave the full out-flow capacity of the lake undiminished as a safeguard against flood conditions. The aim of the project is not alone to restore the loss of navigable depth due to a diversion of 10,000 second feet at Chicago (5½ inches), but to maintain the lake at the highest practicable safe stage. By the manipulation of the outflow computations show 19½ inches gain for the record low water year 1895; over 21 inches gain for the ten-year period 1893-1902; and over 12 inches betterment for the normal supply period 1907-1916.

[fol. 442] The lower limit of slack-water betterment is at the Galops Rapids below Ogdensburg, New York, Navigation betterment below

these rapids is secured by impounding in Lake Ontario the excess supply of the flood months March, April, May and June, and holding this reservoired water for release in the fall months August to November, inclusive. It is found that, while Chicago takes away 10,000 second feet, this is replaced by 9,000 second feet of impounded water in September, 16,000 second feet in October and 20,000 second feet in November. The lower St. Lawrence is dependent for good volume of flow on Lake Ontario water only in these fall months. The Ottawa River entering the St. Lawrence at Montreal has a May flow of 150,000 second feet dwindling to perhaps 20,000 second feet in September, October and November.

Budgeting Lake Ontario water aids water-power by greater uniformity of flow. The attenuated January-February flow is diminished by 10,000 second feet for Chicago, and 17,000 second feet of impounded water more than restores the loss.

The two channels of the Galops Rapids are natural Sluiceways controlling the outflow of Lake Ontario. The Canadian Channel will remain unobstructed. The non-navigable American Channel, [fol. 443] carrying 43 per cent of the outflow, will be throttled by 1,020 feet in length of regulating works. The bottom is bed limestone, probably over-lain in part of glacial drift. The works are placed at the head of this channel. The gates consist of wickets, dropped from five 200-foot span steel bridge platforms. Some increase in outflow capacity of the American Channel is recommended.

9. The special Board of Waterway from Lockport, Ill., to the Mouth of the Illinois River, etc., reported that it would require $150,000 to build works in the Niagara River, and $325,000 for works in the St. Clair River to compensate in Lakes Michigan, Huron and Erie for a lowering of their levels due to the diversion of 10,000 second feet, with $15,000 annually for maintenance.

10. The Sanitary Trustees are very anxious to have a determination at this time of the amount of water the United States will permit to be diverted from the Lake. It seems to be admitted now by all concerned that this matter should be settled by Act of Congress. For example, see page 6, House Doc. 762, 63d Cong., 2d Session, from which the following is quoted:

"Further the Board believes that the total volume of water to be [fol. 444] diverted from the natural discharge channels of the Lakes should be definitely fixed by Congress; that a project with estimate of cost for works necessary to compensate for such diversion should be prepared to the satisfaction of the Chief of Engineers and the Secretary of War; that before any diversion is made beyond that at present existing, the State of Illinois, shall transfer to the Secretary of War the funds necessary for such works as given by the approved estimate of cost; that the works shall be built by the United States with the funds so provided; and that the control and maintenance of such works shall be in and at the cost of the United States."

11. The circumstances that the State of Illinois is now engaged in constructing a navigable link between the Sanitary District Canal

and the Illinois River at Utica makes it extremely desirable that an early determination be made of the amount of flow to be authorized permanently from Lake Michigan. Upon the amount of flow so au-
[fol. 445] thorized will depend to a large extent the character of the improvements which will be necessary to provide an 8 foot channel in the Illinois River should that depth be authorized by Congress.

12. In the letter from the Chief of Engineers dated March 25, 1920 (E. D. 28918) hereinbefore referred to, I was inforced that "at a conference with representatives of the Chicago Sewage Disposal Commission and the Sanitary District Trustee" (sic), it was agreed that the Trustees of the Drainage Canal and the Sanitary Officers of the State would make a study to ascertain what could be accomplished in regard to sewage purification before the sewage was allowed to enter the Drainage Canal or the Illinois River, and the results of such study communicated to the Chief of Engineers through the District Engineer at Chicago. In this same letter I was instructed to cooperate with the Trustees in their study of the case and to render such assistance as I was able, the study to be made "with the idea of withdrawing the least amount of water from Lake Michigan which would be necessary for the purpose."

13. In accordance with the instructions of the Chief of Engineers
[fol. 446] as contained in his letter of March 25, 1920 above referred to, I have held numerous conferences with the Officials of the Sanitary District with regard to their plane for sewage treatment. During the past year there has been considerable change in the official personnel of the Sanitary District, especially among those actively engaged in formulating plane for their sewage treatment system. Among those are the President Chief Engineer, General Counsel and a number of Trustees, considering these conditions the progress made has been very satisfactory.

14. In regard to the contention of the Sanitary District that it is necessary to divert more than 4,167 cubic feet per second in order to avoid contamination of the City water supply and consequent epidemics, I was empowered in a memorandum of the Secretary of War for the Chief Engineers dated July 21, 1920 to say "that if Judge Landis' decree is accepted as final, the War Department will issue no permit, since it is without legal power to do so, but will ask no further orders from the Court to enforce the limitation so long as the City of Chicago proceeds with dispatch to prepare plans and put them into process of execution for its sewage system. If the City of Chicago then prepares plans and consents to the War De-
[fol. 447] partment having current knowledge of its activity, either by reports to the courts or otherwise, the situation will be under the control of Judge Landis until the whole problem is disposed of. If however, the City of Chicago proposes to appeal the case and taken no steps pending the appeal to cure the trouble, Colonel Judson should be instructed to make no concessions or promises of any kind." This memorandum of the Secretary of War was obtained through the Chief of Engineers at my solicitation for use whenever Judge Landis decides to finish the hearing on Attorney Adcock's arguments for

allowing a total diversion of 10,000 second feet. In this connection Mr. Odcock was making the argument that the War Department would be arbitrary in acting on the findings of the court, and a statement was desired which would show that the Secretary of War would not be arbitrary in the matter.

15. On January 17, 1921, a formal conference was held between Mr. Chas. F. Clyne, United States Attorney, and myself representing the United States and the Trustees of the Sanitary District, their attorneys, Consulting Engineer and Chief Engineer. At this conference attention was invited o the Memorandum of the Secretary [fol. 448] of War for the Chief of Engineers dated July 21, 1920, above referred to, copies of which were furnished the Attorneys for the Sanitary District. The Trustees agreed to take under advisement the proposition of the Secretary of War as set forth in his memorandum and to submit an answer thereto at a later date. At this conference an agreement was reached with the Sanitary District authorities that I be furnished with an outline of their present plans for sewage treatment. A copy of the memorandum furnished in accordance with the above agreement giving an outline of the work already completed, that now under way and proposed, and indicating the probable future policy of the Trustees, is enclosed herewith.

16. A second conference was held on February 7, 1921, at which the United States Attorney was represented by his assistant Mr. J. B. Boddie. The proposal of the Secretary of War as embraced in the last paragraph of his memorandum of July 21, 1920 (E. D. 98093/657), was discussed and the Sanitary Trustees stated that they were unable to accept the proposition that Judge Landis' decree be accepted as final. On the other hand they stated that they would pro- [fol. 449] ceed diligently in the preparation and execution of plans for the treatment of sewage within the Sanitary District. They stated that since the conference of January 17, 1921, they had prepared their budget and in it had placed some $8,000,000 for sewage treatment operations, and that in subsequent budgets they would continue to provide for work upon a large scale to carry into effect plans already prepared or now being prepared for sewage treatment. They estimated that depending upon conditions in the labor and material market the entire cost of such treatment would be in excess of $100,000,000 and perhaps as much as $140,000,000 but stated that they were confident that they could provide this sum so that in somewhat less than 25 years they would be able to at least carry out the program adopted August 7, 1919, and perhaps do even better than was proposed in that program.

17. It was understood that the matter before Judge Landis would be proceeded with regardless of the more or less futile negotiations that have been in progress with reference to the proposition of the Secretary of War that the decree of Judge Landis be accepted as final. Mr. Boddie stated that he understood the situation and understood it to be the duty of the United States Attorney's office to proceed with [fol. 450] efforts on its part to secure the formulation and entering

of the formal decree by Judge Landis, opposing any efforts of the Sanitary District to procure a modification of the decree. It may of course be regarded as a fact that the Sanitary Trustees will appeal from the decree of Judge Landis if it is entered without modification, satisfactory to them.

18. The Chief Engineer of the Sanitary District, at the conference of February 7, 1921, informed me that it was the intention of a committee of Trustees and employes of the Sanitary District, including himself, to visit Fort Worth and Houston, Texas, and other localities, at an early date, to inspect activated sludge plants in course of construction or operation and suggested that I accompany them. This I subsequently undertook to do but my travels were interrupted by illness.

19. While the Sanitary District doubtless has authority under existing state laws to proceed with its sewage treatment program, in an excess of caution it has caused bills to be introduced in the State Legislature for explicit authority to construct the proposed sewage treatment works, in accordance with the accompanying memorandum, and the controlling works in the Niagara and St. Lawrence [fol. 451] Rivers as well, in accordance with the projects of Mr. Francis C. Shenehon, hereinbefore referred to. These bills are still pending with good prospects that they will be passed.

Opposing interests are also endeavoring to secure legislation to limit the bonding power of the Sanitary District, by requiring that each bond issue be subject to a referendum.

20. In the meantime the Sanitary Trustees are proceeding energetically with their plans for sewage treatment and disposal as outlined in enclosed memorandum. Since the date of their report they have acquired 180 acres of land located on the North Shore Channel as a site for their proposed North Side purification plant.

21. The progress made by the Sanitary District is well illustrated by Exhibits E and F constituting part of enclosure showing their budget appropriation for 1921 and their expenditures during the ten year period 1910-1920. During the last named period the expenditure for sewage treatment works has amounted to approximately $9,400,000. Their budget for 1921 provides $6,500,800 for the completion of old projects and $3,242,500 for new projects.

22. The program of the Sanitary District, if carried out, will [fol. 452] insure the practicability of keeping the volume of water diverted from Lake Michigan within limits which it is hoped all concerned will finally deem reasonable.

W. V. Judson, Colonel, Corps of Engineers, Divn. Engr., N. W. Divn. 1 encl.

1911—St. Clair Flats canal interpolated.

[fol. 464] CHRISTIE EX. 4—Apr. 26/23

Summary of Statement of Resources and Expenditures of the Sanitary District of Chicago under 1922-1945 Construction Program

Based Upon Plants Going Into Operation as Follows, viz:

Desplaines	1923
Calumet	1923
Corn Products	1927
North Side	1928
Stock Yards	1932
West Side	1940
South West Side	1945

Resources:		
Taxes—Net	$211,850,000	
Sale of bonds—Net	60,949,000	
		$272,799,000
Contra:		
New Construction	$106,300,000	
Ad. Maintenance & Operation	106,400,000	
Interest on Bonds	59,768,880	
Surplus	330,120	
		$272,799,000

NOTE.—Bonds outstanding Jan. 2, 1946	$84,050,000
Maximum bonding capacity Jan. 2, 1946	99,000,000

Haskell, No. A Cross-Examination ..... V 2098
Hayford, No. A Cross-Examination ..... V 3106
Letters and Permits, Various ..... VI 3569-3588
Schoder, Nos. 1-13, inclusive ..... VII 683-694
Stearns, Nos. 1-3, inclusive ..... VII 568-583
Turner, No. 1 ..... VII 681
Williams, Nos. 1-35, inclusive ..... VII 59-567
Williams, Nos. 36-42, inclusive ..... VII 703-829
Wisner, Nos. 1-14F, inclusive ..... VII 697-702

Exhibits, described:
Adams No. 1, Death Rates—All causes 1887-1912 .....
..... VII 661; III 13[illegible]

Volume and Page of Printed Record

Exhibits, described—Continued:
Introduced (Adams)....III 1359
Adams No. 2, Plotting Death Rates, 1860-1912....VII 662; III 1363
Introduced (Adams)....III 1362
Adams No. 3, Air and Water Death Rates....VII 663; III 1365
Introduced (Adams)....III 1365
Adams No. 4, Distribution, Sex and Age, Typhoid..VII 664; III 1367
Introduced (Adams)....III 1367
Adams No. 5, Effect of Canal on Death Rate....VII 665; III 1368
Introduced (Adams)....III 1368
Adams No. 6, Map of Manufacturing Zone....VII 666; III 1370
Introduced (Adams)....III 1369
Adams Nos. 7 and 8, Federal Boat Forms..VII 667, 668; III 1374, 1375
Introduced (Adams)....III 1374
Adams No. 9, Price of Pig Iron and Steel....VII 669; III 1383
Introduced (Adams)....III 1381
Adams No. 10, Steel in England and United States....
....VII 671; III 1387
....III 1386
Introduced (Adams)....
Adams No. 11, Prices, Light and Heavy Steel....VII 673; III 1389
Introduced (Adams)....III 1388
Adams No. 12, Prices, Iron and Steel....VII 675; III 1393
Introduced (Adams)....III 1392
Adams No. 13, Summary Tables—Losses....VII 677; III 1401
Introduced (Adams)....III 1401

Attached to Bill of Complaint:
No. A, War Department Permit, May 8, 1899....VII 1
Permits 200,000 cubic feet per minute.
No. B, War Department Order, April 9, 1901....VII 2
Orders observance of 1899 Permit.
No. C, War Department Letter, July 23, 1901....VII 3
Grants 300,000 cubic feet per minute between hours of 4 P. M. and midnight.
No. D, War Department Permit, Dec. 5, 1901....VII 4
Permits not to exceed 250,000 cubic feet per minute throughout 24 hours.
No. E, War Department Permit, Jan. 7, 1903....VII 5
Permits 350,000 cubic feet per minute till March 31, 1903.
No. F, Sanitary District Letter, Feb. 5, 1912....VII 6
Application for 10,000 C. F. S.
No. G, War Department Letter....VII 7
Reply to Application for 10,000 C. F. S.

Attached to Answer of Sanitary District:
No. A, Copy of Act of May 29, 1899....VII 19
Creating the Sanitary District and Amendments thereto.
No. B, Outline Map of Chicago River and Branches....VII 21

Volume and Page of Printed Record

Exhibits, described, Attached to Answer of Sanitary Dist.—Continued:
No. C, War Department Letter, March 14, 1907.....VII 23
Relates to Reversal of Flow of Calumet River.
No. D, War Department Letter, Sept. 11, 1907.....VII 26
Permit to construct North Shore Channel.
No. E, War Department Letter, June 30, 1910.....VII 27
Permit to construct Calumet Sag Channel.
No. F, Memorial to Congress on the subject of The Illinois and Michigan Canal Laws Extra Session. 1826, p. 97....VII 29
No. G, Ordinance (June 5, 1865) for cleansing Chicago River .....VII 31
No. H, Sanitary District Letter, June 16, 1896.....VII 32
Application for Improvement of Chicago River, also Map of Chicago River accompanying same.
No. I, War Department Letter, July 3, 1896.....VII 37
Permit for the Improvement of Chicago River.
No. J, Sanitary District Letter, April 26, 1900.....VII 38
Application for Improvement of Chicago River.
No. J1, Sanitary District Letter, June 7, 1900.....VII 39
Relation to Improvement of Chicago River.
No. K1 and K2, Maps of Chicago River, 18th to 31st Sts. .....VII 41, 42
Sent to Secretary of War June 7, 1900.
Discussed (Cooley) .....III 1744, 1745
No. L, War Department Letter, June 11, 1900.....VII 43
Permit to Improve Chicago River.
No. L1, War Department Letter, July 11, 1900.....VII 44
Permit to Improve Chicago River.
No. M, Map of Sanitary District of Chicago, 1913.....VII 47

Complainant "A"—See "Shenehon Exhibit R."
Complainant "B"—See "Shenehon Exhibit I."
Complainant "N"—See "Shenehon Exhibit J."
Complainant No. 1, Feb. 15, 1909.
Also U. S. Ex. No. 1, also Government No. 1.....VII 49
Discharge Curve—St. Clair River:
Introduced (Noble) .....I 7
Discussed (Haskell) .....I 45-46
Discussed (Keller) .....I 228
Discussed (Noble) .....I 7-12, 28
Discussed (Ray) .....V 2817, 2818, 2848
Discussed (Sabin) .....I 163-165, 195
Discussed (Shenehon) .....
....I 287, 289, 294, 296; V 3129, 3137, 3141, 3325-3327, 3335
Discussed (Wheeler) .....I 95
Discussed (Williams) .....II 624, 636
Discussed (Wilson) .....I 55

Volume and Page of Printed Record

Exhibits, described—Continued:
Complainant No. 2, Feb. 15, 1900.
Also U. S. Ex. No. 2, also Government No. 2.....VII 51

Discharge Curve—St. Lawrence River:
Introduced (Noble).....I 10
Discussed (Haskell).....I 45-46
Discussed (Keller).....I 232
Discussed (Noble).....I 10-12, 28
Discussed (Ray).....V 2817, 2818, 2848
Discussed (Sabin).....I 163, 171
Discussed (Shenehon).....
.....I 287, 294, 295, 307, 308; V 3137, 3184, 3199, 3200, 3254
Discussed (Wheeler).....I 106
Discussed (Williams).....II 624, 636, 747
Discussed (Wilson).....I 55

Complainant No. 3, Feb. 15, 1900.
Also U. S. Ex. No. 3, also Government No. 3.....VII 53

Discharge Curve—International Bridge:
Introduced (Noble).....I 10
Discussed (Haskell).....I 45-46
Discussed (Keller).....I 233
Discussed (Noble).....I 10-12, 28
Discussed (Ray).....V 2817, 2818, 2848
Discussed (Sabin).....I 163
Discussed (Shenehon).....
.....I 287, 294, 295, 300, 303, 308; V 3116, 3137, 3147, 3370
Discussed (Wheeler).....I 102
Discussed (Williams).....II 624, 636, 749, 882
Discussed (Wilson).....I 55

Complainant No. 4, Feb. 15, 1900.
Also U. S. Ex. No. 4, also Government No. 4.....VII 55

Discharge Curve—Open Section:
Introduced (Noble).....I 10
Discussed (Haskell).....I 45-46
Discussed (Keller).....I 233
Discussed (Noble).....I 10-12, 28
Discussed (Ray).....V 2817, 2818, 2848
Discussed (Sabin).....I 163
Discussed (Shenehon).....I 287, 294, 301, 306, 308; V 3137
Discussed (Wheeler).....I 102
Discussed (Williams).....II 624, 636, 740
Discussed (Wilson).....I 55

Complainant No. 5, April 19, 1900 (not printed).
General Chart of the Great Lakes:
Introduced (Townsend).....I 73
Referred to as Complainant's Ex. No. 6 (Williams).....II 590

Volume and Page of Printed Record

Exhibits, described—Continued:
Complainant No. 5, May 24, 1900.....VII 57
Hydrograph Great Lakes:
Introduced (Keller).....I 249
Discussed (Shenehon).....I 355, 361
Discussed (Williams).....II 926
Complainant No. 6 (not printed).
Current Meter Tests:
Introduced (Shenehon).....I 310
Discussed (Williams).....II 913
Defendant's Exhibit A (not printed).
Chart of the Detroit River:
Introduced (Shenehon).....I 335
Defendant's Exhibit B.....IV 2485
Plate 12 following page 5400, Rept. 1900:
Discussed (Shenehon).....I 341-345
Identified (Shenehon).....I 345
Defendant's Exhibit C.....IV 2477
Plate 7 following page 5360, Rept. 1900:
Introduced (Shenehon).....I 345
Defendant's Exhibit D.....IV 2475
Plate 6 following page 5360, Rept. 1900:
Introduced (Shenehon).....I 353
Defendant's Exhibits E, F, G, H, I—See "Williams' Exhibit 26."
Tables of Levels of Great Lakes:
Introduced (Shenehon).....I 354
Freeman No. 1, Studies Relative to
Chicago Drainage Canal.....VII 585
Introduced and Discussed (Freeman).....III 1153, 1160, 1171, 1173
Freeman No. 2, Hydrograph of Recording Gage....VII 587; III 1164
Introduced (Freeman).....III 1163
Freeman No. 3, Hydrographs, Huron and St. Clair.....
.....VII 588; III 1168
Introduced (Freeman).....III 1167
Freeman No. 4, Groat on Current Meters.....VII 589-654
Introduced (Freeman).....III 1183
Discussed (Haskell).....V 2673
Discussed (Shenehon).....V 3155
Referred to (Hayford).....V 3089
Freeman No. 5, Time Interval between Gages.....VII 655; III 1190
Introduced (Freeman).....III 1189
Freeman No. 6, Current Velocity Fluctuations.....VII 656; III 1191
Introduced (Freeman).....III 1189

Volume and Page of Printed Record

Exhibits, described—Continued:
Freeman Nos. 7, 8 and 9, Current Pulsations.....
.....VII 657-659; III 1189, 1192-1194
Fuller No. 1, Map of Sanitary District.....VII 679; III 1473
Introduced (Fuller) .....III 1413
Government Nos. 1, 2, 3 and 4—See "Complainant Nos. 1, 2, 3, 4."
Government Nos. A and B—See "Complainant A and B."
Government No. C—See "Richmond No. 1."
Government No. D—See "Richmond No. 2."
Government No. E—See "Richmond No. 3."
Government Nos. F, G, H, and I—See "Shenehon Nos. K, L, M and N."
Government Nos. J, K and L—See "Shenehon Nos. O, P and Q."
Government No. M—See "Shenehon No. T."
Government No. N—See "Shenehon No. J."
Government No. O—See "Shenehon No. S."
Government No. HH (not printed):
Corrected Table Buffalo Gage Readings:
Introduced (Freeman) .....III 1236

Haskell, No. 1, Feb. 17, 1909 (not printed).
Discharge Curves, St. Clair, Niagara, St. Lawrence:
Introduced (Haskell) .....I 46
Discussed (Haskell) .....I 55, 56
Discussed (Williams) .....II 803
Discussed (Wilson) .....I 54

Haskell No. 1, Feb. 3, 1914—See "Shenehon No. B."

Haskell No. 2 (not printed).
Pamphlet "Ritchie-Haskell Direction Current Meter and Haskell Current Meters":
Introduced (Haskell) .....V 2667, 2748

Haskell's No. A.....V 2698
Table of Hypothetical Gage Readings:
Introduced (Haskell) .....V 2697
Discussed (Shenehon) .....V 3256-3262

Hayford Nos. 1, 2, 3, 4 and 5—See "Shenehon Nos. U-1, U-2, U-3, U-4, U-5."
Hayford No. 6—See "Shenehon No. E."
Hayford No. 7—See "Shenehon No. D."
Hayford No. 8—See "Shenehon No. B."
Hayford's No. "A" Cross-Examination Corrected.
Discharge Measurements Niagara River:
Introduced (Hayford) .....V 3108

Moore, Nos. 1-4, inclusive.....V 2884-2888; VII 717-720

Volume and Page of Printed Record

Exhibits, described, Moore, Nos. 1-4, incl.—Continued:
Drainage Canal Discharge Measurements:
Introduced (Moore) ..... V 2879-2890
Discussed (Ray) ..... V 2832, 2847, 2856
Moore No. 5.
Drainage Canal Flow Curve:
Introduced (Moore) ..... V 2890; VII 721
Discussed (Shenehon) ..... V 3174

Ray No. 1—See "Shenehon No. H."
Ray No. 2—See "Shenehon No. F."
Ray No. 3—See "Shenehon No. G."

Richmond No. 1, also "Government C" ..... VII 707-709
Split Section Discharge Measurements:
Introduced (Richmond) ..... V 2940
Introduced (Williams) ..... II 947, 955

Richmond No. 2, also "Government D" ..... VII 711
Still Water Rating Curves:
Introduced (Richmond) ..... V 2940
Introduced (Williams) ..... II 947

Richmond No. 3, also "Government No. E" ..... VII 713
Niagara Discharge Curve:
Introduced (Richmond) ..... V 2941
Introduced (Williams) ..... II 947

Richmond No. 4.
Cross Sections, Split Section:
Introduced (Richmond) ..... V 2941; VII 715

Richmond No. A (not printed).
Percentage Discharge of Verticals (21 sheets):
Introduced (Richmond) ..... V 2966

Richmond No. B (not printed).
Index Velocities and Vertical Curves:
Introduced (Richmond) ..... V 2988

Schoder No. 1 ..... VII 683; III 1536
Haskell Current Meter:
Introduced (Schoder) ..... III 1535
Schoder Nos. 2-12, inclusive ..... VII 684-694; III 1537-1547
Canal at Cornell University:
Introduced (Schoder) ..... III 1536
Discussed (Haskell) ..... V 2969

Volume and Page of Printed Record

Exhibits, described—Continued:
Schoder No. 13 ..... VII 695; III 1548
Summary Table of Tests at Cornell:
Introduced (Schoder) ..... III 1548
Shenehon No. A, also "Williams' Cross 3" ..... VII 723
Plotting Niagara Discharge Measurements:
Introduced (Shenehon) ..... V 3113
Introduced (Williams) ..... II 880, 881
Discussed (Freeman) ..... III 1196, 1203, 1239
Shenehon No. B, also "Haskell No. 1, Feb. 3, 1914" ..... VII 725
Also "Hayford No. 8."
Bridge Section Discharge Curve:
Introduced (Haskell) ..... V 2990
Introduced (Hayford) ..... V 3087
Introduced (Shenehon) ..... V 3114, 3240
Shenehon No. C ..... VII 727
Plotting of 30 Measurements, Niagara River:
Introduced (Shenehon) ..... V 3117
Shenehon No. D, also "Hayford No. 7" ..... VII 729
Open Section Discharge Curve:
Introduced (Hayford) ..... V 3087
Introduced (Shenehon) ..... V 3118, 3240, 3359
Shenehon No. D-1 ..... VII 731
Plotting 89 measurements, Niagara River:
Introduced (Shenehon) ..... V 3359
Shenehon No. E, also "Hayford No. 6" ..... VII 733
Suspension Bridge and Whirlpool Equations:
Introduced (Hayford) ..... V 3080
Introduced (Shenehon) ..... V 3119, 3156, 3191
Shenehon Nos. E1, E2, E3 and E4 ..... VII 807-813
Buffalo Gage Computed from Chippawa:
Introduced (Shenehon) ..... V 3371
Shenehon No. F, also "Ray No. 2" ..... VII 735
Suspension Bridge Discharge Curve:
Introduced (Ray) ..... V 2807
Introduced (Shenehon) ..... V 3120, 3156, 3191
Discussed (Moore) ..... V 2867
Shenehon No. G, also "Ray No. 3" ..... VII 737
Whirlpool Discharge Curve:
Introduced (Ray) ..... V 2806-2808

Volume and Page of Printed Record

Exhibits, described, Shenehon No. G—Continued:
Introduced (Shenehon) .....V 3120, 3156, 3191
Discussed (Moore) .....V 2867

Shenehon No. H, also "Ray No. 1".....VII 739
Relative Fluctuations Whirlpool and Gorge:
Introduced (Ray) .....V 2807
Introduced (Shenehon) .....V 3121, 3190
Discussed (Moore) .....V 2867

Shenehon No. I, also "Complainant B".....VII 741
Relative Fluctuations, Huron and St. Clair:
Introduced (Shenehon) .....V 3122
Introduced (Williams) .....II 943, 949, 952
Discussed (Freeman) .....III 1226

Shenehon No. J, also "Complainant N".....VII 743
Relative Fluctuations, Erie-Ontario:
Introduced (Freeman) .....III 1224
Introduced (Shenehon) .....V 3122

Shenehon Nos. K, L, M, N (Three Curve Series).....VII 747-751
Also "Government F, G, H, I":
Introduced (Shenehon)..V 3123, 3215, 3217, 3240, 3274, 3366, 3367
Introduced (Williams) .....II 949, 966, 969
Discussed (Freeman) .....III 1219

Shenehon Nos. O, P and Q (One Curve Series).....VII 753-757
Also "Government J, K and L":
Introduced (Shenehon) .....V 3086, 3125
Introduced (Williams) .....II 949, 970, 977
Discussed (Freeman) .....III 1200-1203

Shenehon No. R, also "Complainant A".....VII 759
Observed and Computed Lake Elevations:
Introduced (Shenehon) .....V 3125, 3157, 3329
Introduced (Williams) .....II 933-936

Shenehon No. S, also "Government O".....VII 761
Discharge Curve, St. Lawrence, 1912:
Introduced (Shenehon) .....V 3127
Discussed (Stearns) .....II 1003
Discussed (Freeman) .....III 1216

Shenehon No. T, also "Government M".....VII 763
St. Lawrence, Niagara Discharge Comparison:
Introduced (Freeman) .....III 1207, 1214, 1236
Introduced (Shenehon) .....V 3128, 3147
Discussed (Stearns) .....II 1143

Volume and Page of Printed Record

Exhibits, described—Continued:
Shenehon Nos. U-1, U-2, U-3, U-4 and U-5.....VII 765-769
Also "Hayford's 1, 2, 3, 4 and 5."
Also "Williams' Memo. Cross-Exam. A":
Introduced (Hayford).....V 3086, 3093
Introduced (Shenehon).....V 3128, 3129
Introduced (Williams).....II 882

Shenehon No. V.....VII 771
Observed and Computed Chippawa Gage:
Introduced (Shenehon).....V 3350, 3366

Shenehon Cross-Examination A and B.
See Williams' Nos. 39-A and 39-B.

Shenehon Cross-Examination C and D.
See Williams' Nos. 39-C and 39-D.

Shenehon Cross-Examination E-1, E-2, E-3, E-4.
See Williams' 39-E1, 39-E2, 39-E3 and 39-E4.

Stearns No. 1.....VII 568-574
Seven (7) Tables comparing River Discharges:
Introduced (Stearns).....II 1005-1015
Data used as basis of (Stearns).....II 1090-1092
Discussed Table E (Stearns).....II 1126-1129

Stearns No. 2.....VII 575-581
Plotting of Exhibits 1 and 3:
Introduced (Stearns).....II 1102-1106, 1134-1140

Stearns No. 3.....VII 583
St. Clair and St. Lawrence Discharge:
Introduced (Stearns).....II 1107

Turner No. 1.....VII 681
Vertical Velocity Curves, St. Mary's River:
Introduced (Turner).....III 1571, 1575
Discussed (Haskell).....V 2670

U. S. Nos. 1, 2, 3 and 4—See Complainant 1, 2, 3 and 4.
Williams No. 1, Chart of Lake Superior.....VII 59
Introduced (Williams).....II 592
Williams No. 2, Chart No. 3, St. Mary's River.....VII 61
Introduced (Williams).....II 592
Williams No. 3, Chart No. 2, St. Mary's River.....VII 63
Introduced (Williams).....II 593
Williams No. 4, Chart No. 1, St. Mary's River.....VII 65
Introduced (Williams).....II 594
Williams No. 5, Chart Lake Michigan.....VII 67

Volume and Page of Printed Record

Exhibits, described, Williams No. 5—Continued:
Introduced (Williams) ..... II 594
Williams No. 6, Chart Lake Huron..... VII 69
Introduced (Williams) ..... II 595
Williams No. 7, Chart St. Clair River..... VII 71
Introduced (Williams) ..... II 596
Williams No. 8, Chart Lake St. Clair..... VII 73
Introduced (Williams) ..... II 598
Williams No. 9, Chart Detroit River..... VII 75
Introduced (Williams) ..... II 598
Williams No. 10, Chart Lower Detroit River..... VII 77
Introduced (Williams) ..... II 599
Williams No. 11, Chart Lake Erie..... VII 79
Introduced (Williams) ..... II 601
Introduced (Ripley) ..... III 1350
Williams No. 12, Chart Buffalo Harbor..... VII 81
Introduced (Williams) ..... II 601
Williams No. 13, Chart Niagara River..... VII 83
Introduced (Williams) ..... II 602
Williams No. 14, Chart Lake Ontario..... VII 85
Introduced (Williams) ..... II 602
Williams No. 15, Chart 6, St. Lawrence River..... VII 87
Introduced (Williams) ..... II 603
Williams No. 16, Chart 5, St. Lawrence River..... VII 89
Introduced (Williams) ..... II 603
Williams No. 17, Chart 4, St. Lawrence River..... VII 91
Introduced (Williams) ..... II 603
Williams No. 18, Chart 3, St. Lawrence River..... VII 93
Introduced (Williams) ..... II 603
Williams No. 19, Chart 2, St. Lawrence River..... VII 95
Introduced (Williams) ..... II 604
Williams No. 20, Chart 1, St. Lawrence River..... VII 97
Introduced (Williams) ..... II 604
Williams No. 21, Tabulation St. Clair River..... VII 99-105
Discharge Measurements, 1890-1902, 1908:
Introduced (Williams) ..... II 616-620
Williams No. 22, Hydraulic Data on St. Clair River..... VII 106-111
Introduced (Williams) ..... II 617
Williams No. 23, Hydraulic Data on St. Clair River..... VII 112-148
Introduced (Williams) ..... II 617
Williams No. 24, Summary Niagara River..... VII 149-153
Discharge Measurements:
Introduced (Williams) ..... II 617
Material introduced (Shenehon) ..... I 291
Referred to (Hayford)..... V 3100
Williams No. 25, Summary St. Lawrence River..... VII 154, 155
Discharge Measurements:
Introduced (Williams) ..... II 617

Volume and Page of Printed Record

Exhibits, described—Continued:
Williams No. 26, Water Surface Elevation of Great Lakes.....VII 156-167
Introduced (Williams).....II 618
Williams No. 27, Water Surface Elevations, Lake St. Clair and Detroit River.....VII 168-170
Introduced (Williams).....II 618
Williams No. 28, Daily Water Surface Elevations, Lakes St. Clair and Huron.....VII 171-180
Introduced (Williams).....II 618
Williams No. 29, Daily Water Surface Elevations, Lake Erie.....VII 181-200
Introduced (Williams).....II 618
Williams No. 30, Monthly Water Surface Elevations, Oswego and Ogdensburg.....VII 201-205
Introduced (Williams).....II 618
Williams No. 31, Rainfall on Great Lakes.....VII 206-210
Introduced (Williams).....II 619
Williams No. 32, Wheeler's Report on Rainfall and Evaporation.....VII 211-247
Introduced (Williams).....II 619
Introduced (Stearns).....II 1008
Williams No. 33, Report of International Waterways Commission, 1900.....VII 248-347
Introduced (Williams).....II 619
Williams No. 34, Williams Computations.....VII 349-547
Introduced (Williams).....II 623
Described (Williams).....II 623-744
Corrected (Williams).....II 986
Williams No. 35, Plottings of Water Surface Elevations during gagings.....VII 548-567
Introduced (Williams).....II 728
Williams No. 36, Direction Measurements International Bridge (Table).....VII 793
Introduced (Williams).....VI 3510-3512
Plotting of.....VII 802-805
Williams No. 37, Field Data on Vertical Curve, Span 6, Station 4/12, International Bridge.....VII 796
Introduced (Williams).....VI 3516
Williams No. 38, Plotting Vertical Curves, Section Oakfield.....VII 797
Introduced (Williams).....VI 3518
Introduced (Shenehon).....V 3222
Williams Nos. 39-A and 39-B.....VII 799, 801
Also "Shenehon Cross-Examination A and B."
Plotting Hourly Water Levels, Buffalo and Chippawa.
Introduced (Shenehon).....V 3222
Introduced (Williams).....VI 3519

Volume and Page of Printed Record

Exhibits, described—Continued:

Williams Nos. 39-C and 39-D.....VII 802-805

Also "Shenehon Cross-Examination C and D," Table of Direction Measurements on Vertical Curves, Niagara River:
Introduced (Shenehon).....V 3304
Plotting of.....VII 793

Williams Nos. 39-E1, 39-E2, 39-E3 and 39-E4.....VII 807-813

Also "Shenehon Cross-Examination E-1, E-2, E-3, E-4"
Plotting Buffalo Gage Computed, from Chippawa:
Introduced (Shenehon).....V 3371

Williams No. 40, Analysis of Method of Locating Current Meter (Diagram).....VII 815
Introduced (Williams).....VI 3522-3526, 3500

Williams No. 41, also "Williams Cross 1."
Discharge Measurements, Niagara River, 1907, 1908....VII 817-821
Introduced (Williams).....II 847
Discussed (Williams).....II 852, 855, 863

Williams No. 42, also "Williams Cross 4."
Hourly Water Levels, Buffalo and Chippawa.....VII 822-829
Introduced (Williams).....II 897

Williams Cross No. 1—See "Williams 41."

Williams Cross No. 2 (not printed).
Hourly Water Levels, Buffalo, 1908:
Introduced (Williams).....II 857
Discussed (Williams).....II 857, 861, 862

Williams Cross No. 3—See "Shenehon A."

Williams Cross No. 4—See "Williams 42."

Williams Memo Cross No. A—See "Shenehon U1-U5."

Wisner No. 1, Map of Sanitary District.....VII 697
Introduced (Wisner).....III 1594

Wisner No. 2, Map of Cook, Will and DuPage Counties.....VII 699
Introduced (Wisner).....III 1603

Wisner No. 3, Typhoid Fever Chart.....VII 701
Introduced (Wisner).....III 1624
Discussed (Wisner).....III 1667-1669

Wisner No. 4, Typhoid Fever Chart.....VII 703
Introduced (Wisner).....III 1625

Wisner No. 5, Report of Wisner to Sanitary District, Oct., 1911 (not printed).
Introduced (Wisner).....III 1638

Wisner No. 6, Hydrograph Lake Michigan.....VII 705
Introduced (Wisner).....III 1644
Discussed (Wisner).....III 1693

Volume and Page of Printed Record

Exhibits, described—Continued:
Wisner Nos. 7, 8, 9, 10 and 11,
Five (5) Maps of the Chicago River.....VII 773-781
Introduced and Discussed (Wisner).....VI 3422-3427
Wisner No. 12, Outline of Docks, Prior to Improvement Chicago River.....VII 783
Introduced (Wisner).....VI 3430
Wisner No. 13, Similar to Wisner No. 12.....VII 785
Except subsequent to Improvement.
Introduced (Wisner).....VI 3430
Wisner Nos. 14—A, B, C, D, E and F.....VII 787-792
Chicago Drainage Canal Tests.
Introduced (Wisner).....VI 3434, 3467, 3469
Wisner No. 14—G, (not printed).
Chart 34—A Drainage Canal Tests.
Introduced (Wisner).....VI 3463

F

Farquhar, Major F. W. (Ripley).....III 1288
Farrans Point, Excavation and Fall (Ripley).....VII 97; III 1340
Filtration—See "Water and Sewage Purification."
Fish Industry, Increase in (Cooley).....III 1756
Fish Industry, Increase in (Wisner).....III 1615, 1616, 1659

Floats:
Accuracy of meter established by (Haskell).....V 2669, 2700
Accuracy of meter established by (Williams).....II 785
Applicability to large rivers (Williams).....II 790
Compared with current meters (Williams).....II 766, 782
Description of rod (Williams).....II 570
Double (Haskell).....V 2700, 2702
Double (Williams).....II 784
Francis formula for (Williams).....II 785
Limitations of use (Williams).....II 783
Measurement by, description of (Williams).....II 784
Subject of mathematical uncertainty (Williams).....II 783
Used on Mississippi River (Williams).....II 787
Used on St. Clair River (Noble).....I 27
Vinyard Sound Measurements (Haskell).....V 2666, 2667, 2700
Wisner's George Y., preference for (Williams).....II 791

Fluctuations—See also "Barometric Pressure."
Causes of (Cooley).....III 1785
Causes of (Freeman).....III 1153, 1160-1172
Causes of (Hering).....I 512
Causes of (Shenehon).....V 3188
Causes of (Williams).....II 672, 699

Volume and Page of Printed Record

Fluctuations—Continued:
Changes in—See "Regimen of Lakes."
Definitions of (Williams) ..... II 870
Discharge, relation to (Williams) ..... II 864

Relation of, to sewage purification (Hering) ..... I 556
Toronto Situation (Stearns) ..... II 1065
Washington Plant (Hazen) ..... I 470, 476
Washington System and Cost (Fuller) ..... III 1468
Washington Supply (Phillips) ..... III 1520
Washington Supply, Cost of (Phillips) ..... III 1525
Water borne diseases (Adams) ..... III 1361, 1365

Water wheels as meters (Wisner) ..... III 1660

Waves:
Carrier on Lake Michigan (Cooley) ..... III 1784
Tidal on Hudson River (Cooley) ..... III 1785

Wave Propagation—See "Lag."

Weirs—See also "Cornell Canal."
Discussion on experiments of Bazin, Francis, Fteley and Stearns (Haskell) ..... V 2680-2687

Weitzel Lock—See "Locks."

Welland Canal:
Depth (Kent) ..... V 3012
Diversion through (Keller) ..... I 243
Diversion through (Shenehon) ..... I 374, 376
Diversion through (Wheeler) ..... I 111
Work under way on (Ray) ..... V 2800

Wenter, Frank, report of, 1892 ..... IV 2335
West Side Project B (Fuller) ..... III 1433

Wheeler, Eben S.:
Qualifications of (Wheeler) ..... I 87
Report on Great Lakes, "U. S. Engr. Rept." ..... I 146-149, 151

Whirlpool Gage—See "Gages."

Wickwire Section:
Cross section (Richmond) ..... VII 715
Criticism of (Freeman) ..... III 1208
Criticism of (Williams) ..... II 946
Curvature, effect of (Haskell) ..... V 2666
Current, corrections for direction (Richmond) ..... V 2998
Deflections at, sounding (Richmond) ..... V 2942, 3017

	Volume and Page of Printed Record
Wickwire Section—Continued:	
Depth at (Richmond)	V 3019
Description of (Haskell)	V 2665
Discharge curve (Richmond)	VII 713
Discharge measurements at (Richmond)	V 3014, 3018
Discharge measurements at (Williams)	II 944, 948, 956
Flow at (Richmond)	V 2944, 2947, 2998
Location (Williams)	II 946
Meters, position of (Richmond)	V 3002
Panels at (Richmond)	V 3015
Purpose of measurements at (Ray)	V 2848
Purpose of measurements at (Richmond)	V 2935, 3013
Purpose of measurements at (Shenehon)	I 284
Soundings at (Richmond)	V 3015, 3017
Transverse velocity curves (Richmond)	VII 715
Turbulence (Shenehon)	V 3143, 3154
Width at (Richmond)	V 3015
Report on Measurements (Richmond)	VII 707-709
Records of Discharge at (Richmond)	VII 707-709
Willard, Col. J. H., 1900-1901 Reports	IV 2185, 2383
Willard, E. W., Historical Situation; I. & M. Canal	IV 2102
Williams, Benezette, report of 1892	IV 2351
Williams, Gardner S.:	
Consulting practice (Williams)	II 572, 577
Engineer, Detroit Board of Water Com. (Williams)	II 566
Expert witness (Williams)	II 576
Methods of computation—See "Increment—Methods of Obtaining."	
Qualifications (Williams)	II 566-569, 573-579
University of Michigan, Professor at (Williams)	II 576, 572
Wilson, Maj. J. H., Report of 1867	IV 2240
Wilson, W. Edward, Qualifications of (Wilson)	I 49
Wind:	
Effect on Lake Levels (Freeman)	III 1161
Errors due to (Hayford)	V 3095
Effect of on Lake Erie (Wheeler)	I 141
Velocities, monthly means (1860-1898):	
Lake Superior	VII 246
Lake Michigan-Huron	VII 246
Lake St. Clair	VII 247
Lake Ontario	VII 247
Windmill Point Gage—See "Gages."	
Wisner, George M.:	
Qualifications (Wisner)	III 1592-1594, 1694
Report of Oct., 1911 (Wisner)	III 1636-1639

	Volume and Page of Printed Record
Wisner, George Y., Reports of 1883, 1884 (U. S. Eng. Rep.)	IV 2154, 2155
Winter Sections, Galops Rapids (Shenehon)	V 3172
World's Fair Sewage Station (Hazen)	I 463
Worthen, Chief Eng. Sanitary District Report of 1891	IV 2330
Wright, Benj., Report of 1837	IV 2085
Y-term in 1912 St. Clair River Equation	
Changes in (Ray)	V 2828
Data used in determining (Ray)	V 2824
Discharge, relation to (Ray)	V 2826
Explanation of term (Ray)	V 2820, 2843, 2855
Formula including (Ray)	V 2820-2824
Increment, relation to (Ray)	V 2824-2827
Variation in over period of years (Ray)	V 2844

VOL. I.

CLASSIFIED TABLE OF CONTENTS.

ALFRED NOBLE'S TESTIMONY FOR COMPLAINANT.

	Page
Direct examination	1-16
Cross-examination	16-28
Re-direct examination	28-30
Chicago Diversion:	
Effect of, on:	
Detroit River	10
Great Lakes	4-5
Lake Erie	10, 16
Lakes Michigan-Huron	9, 16, 21
Lake Ontario	10, 16
Lake St. Clair	5, 10, 16
Navigation in Great Lakes	21-25, 28, 29
Niagara River	10
St. Clair River	6, 10
St. Lawrence River	10
St. Mary's River	10
Use of Complainant's Exhibits 1, 2, 3, 4 to determine effect of, on Lakes	28
Discharge Measurements, skill and accuracy of, on rivers	15, 27
Evaporation, value of data on, from Great Lakes	14
Exhibits:	
Complainant's No. 1 introduced and marked	7
Complainant's Nos. 2, 3 and 4 introduced, marked and discussed	10, 12
Increment:	
Discussion of correctness of, shown on Complainant's Exhibit No. 1.	7-9
Discussion of correctness of, shown on Complainant's Exhibits Nos. 2, 3 and 4	10
Formula for determination of	8
Value of, for Niagara River	13
Lake Erie:	
Cost of regulating works to control elevation of	21, 29
See "Chicago Diversion."	
Variation in elevation between, and Lake Huron	26
Lake Huron.	
Effect of increasing the discharge of Lake Superior on	18, 20
See "Chicago Diversion."	
Variation in elevation between, and Lake Erie	26
"Lowering," meaning of word	5
Navigation, effect of Chicago Diversion on	21-25, 28, 29
"Net Supply," meaning of term	5

Niagara River,

Page

See "Chicago Diversion."
Value of increment for 13

Noble, Alfred,

Address 1-2
Education 4
Experience 2
On hydraulics of Great Lakes 2, 3
Occupation 2
Rainfall, value of data on, on Great Lakes 14

Vessels:

Carrying capacity of Lake 25
Carrying capacity of, per inch of draft 15, 25

EUGENE E. HASKELL'S TESTIMONY FOR COMPLAINANT.

Page

Direct examination 30-40
Cross-examination 40-47
Re-direct examination 47-49
Blanchard, Murray, competency of 38

Chicago Diversion:

Areas of lakes, navigation affected by 35
Effect of, on:
Detroit River 36, 43
Lake Erie 40, 41, 42
Lakes Michigan-Huron 35, 40, 41
Lake Ontario 36, 40, 43
Lake St. Clair 36, 42
Niagara River 36, 43, 48
St. Clair River 36, 41
St. Lawrence River 36, 38, 41, 44, 48
St. Mary's River at foot of locks 35
Haskell's source of information on 45
Time required for effect of, on:
Detroit River 39
Lake Erie 39
Lakes Michigan-Huron 39
Lake Ontario 39
Niagara River 39
St. Clair River 39

Page

Detroit River:
Influence of elevations of Lakes Huron and Erie on..... 44
See "Chicago Diversion."
Evaporation, propriety of using existing data on..... 38

Exhibits:
Complainant's Nos. 1, 2, 3, 4, introduced.....45, 46
Haskell's No. 1 introduced and marked for identification..... 46
Haskell Current Meters, used in discharge measurements.....32, 36

Haskell, Eugene E.:
Address..... 30
Education..... 30
Experience..... 31
On hydraulics of Great Lakes..... 31
Source of information on Chicago Diversion..... 45
Occupation..... 30
Increment, definition of..... 49
International Bridge, measurements at..... 37

Lake Erie:
Accuracy of results of measurements on..... 37
Influence on stages of Detroit River, St. Clair River and Lake St. Clair..... 44
See "Chicago Diversion."

Lake Huron:
Accuracy of results of measurements on..... 37
Influence on stages of St. Clair River, Detroit River and Lake St. Clair..... 44
Difference in elevations between, and Lake Erie..... 46
See "Chicago Diversion."

Lake Michigan:
Accuracy of results of measurements on..... 37
See "Chicago Diversion."
Lakes Michigan-Huron, see "Chicago Diversion."
Lake Ontario, see "Chicago Diversion."

Lake St. Clair:
Control of Lakes Huron and Erie on stage of..... 44
See "Chicago Diversion."
"Lowering," meaning of word..... 33
"Net Supply," meaning of term..... 34
Open Section, measurements at..... 37
Precipitation, accuracy of data.....38, 47
Sabin, L. C., competency of..... 36

Page

St. Clair River:
Influence of elevation of Lakes Huron and Erie on 44
See "Chicago Diversion."
St. Lawrence River, accuracy of results of measurements on 37
Three Point Section, measurements at 37
Water measurements, instruments used in 32, 36

W. EDWARD WILSON'S TESTIMONY FOR COMPLAINANT.

Direct examination 49-54
Cross-examination 54-55
Re-direct examination 55-56
Re-cross examination 56-57

Chicago Diversion:
Effect of, on:
Lake Erie 52
Lakes Michigan-Huron 52
Lake Ontario 52
Niagara River 52
St. Lawrence River 52
St. Mary's River 52

Length of time to affect:
Lake Erie 54
Lakes Michigan-Huron 54
Lake Ontario 54
Lake St. Clair 54
Haskell's Exhibit No. 1, used for computing effect of diversion on Great Lakes 54, 55
"Lowering," definition of term 5
"Net supply," definition of term 51

Wilson, W. Edward:
Address 49
Education 49
Experience 49
On hydraulics of Great Lakes 50
Occupation 49

O. H. ERNST'S TESTIMONY FOR COMPLAINANT.

Direct examination 57-64
Cross-examination 64-71

Page

Chicago Diversion:
Effect of, on:
Great Lakes System....59, 67, 68
Lake Erie 61
Lake Michigan 59, 65
Lake Ontario 61
Detroit River, total freight carried through, in 1907.... 62

Ernst, O. H.:
Address 57
Education 57
Experience 57
On hydraulics of Great Lakes.... 57
Name 57
Occupation 57
Sources of information regarding navigation....62, 64

Evaporation:
Consideration of effects of.... 61
Effect of, on Great Lakes....60, 61, 66
Lake Erie, effect of Chicago diversion on.... 61

Lake Michigan:
Causes of seiches on.... 65
Effect of Chicago diversion on....59, 65
Extent of oscillations or seiches on....65, 69

Lakes Michigan-Huron:
Effect on navigation by lowering of.... 70
Mean Lake stage an average of years.... 66
Lake Ontario, effect on, by Chicago diversion.... 61
"Lowered," meaning of term.... 60

Navigation:
Detroit River, total freight carried through, in 1907.... 62
Effect on, by lowering Lakes Michigan-Huron.... 70
Percentages of freight carried east and west.... 63
"Net Supply," meaning of term.... 60
Poe Locks, depth of water in.... 63
Rain Fall, effect of, on Great Lakes....60, 61, 66
Report of Board of International Waterway Commission, Paragraphs 22 and 23.... 69-71

Seiches on Lake Michigan:
Cause of 65
Extent of 65, 69

Vessels:

Page

Dimensions of largest, on Lakes..... 64
Number of deep draft, on Lakes..... 62
Percentage of freight carried in deep draft..... 62
Total freight carried in vessels limited by depth of water..... 62

C. McD. Townsend's Testimony for Complainant.

Direct examination 71-77
Cross-examination 77-83
Re-direct examination 83-85
Re-cross examination 86-87
Ballard's Reef, depth of water at..... 79
Bar Point, depth of water at..... 78, 79
Chicago Diversion, effect of, on water levels in Townsend's "district"..... 75, 76
Complainant's Exhibit No. 5, April 19, 1909:
Location of improved channels in "district"..... 73
Townsend's "districts" marked out on..... 73
Detroit River:
Freight carried through..... 74
Improvements affecting flow of..... 79
Lakes Michigan-Huron, effect of Government improvements on levels of 83
Lime Kiln Crossing, enlargement of cross section..... 83, 84, 86
"Limiting Depths," location of, for large vessels..... 74, 76
Navigation:
Freight carried through St. Clair and Detroit Rivers..... 74
Freight carried through St. Mary's River..... 74
Location of limiting depths or critical places for large vessels..... 74, 76
Policy of Government to improve..... 82
Poe Locks, depth of water at..... 78, 83, 86
St. Clair River, freight carried through..... 74
St. Mary's River, freight carried through..... 74
Townsend, Curtis McDonald:
Address 71
Experience 71
Limits of district in charge of..... 73
Occupation 71
Townsend's "District":
District marked out..... 73
Location of improved channels in..... 73
Vessels:
Comparison of lake and ocean..... 85, 87
Depth to which loaded..... 74, 78
Loading capacity of, per inch of draft..... 77, 81

EBEN S. WHEELER'S TESTIMONY FOR COMPLAINANT.

Page

Direct examination 87-119
Cross-examination 119-150
Re-direct examination 150-155
Bulletin No. 16, Survey of the Northern and Northwestern Lakes..... 137

Chicago Diversion:

Comparison of effects on St. Clair and Detroit Rivers..... 142

Effect of, on:

Great Lakes System, statement by Secretary of International Waterways Commission 142
Lake Erie 90, 141
Lake Huron 90, 99-100, 140
Lake Michigan 90, 99, 140
Lake Ontario 90, 145
Locks of St. Mary's River..... 101
Storage capacity of Lakes Michigan-Huron..... 144-145
St. Clair River..... 90, 92, 100
St. Lawrence River..... 106

Relation of ice in St. Clair River to..... 109, 110
Time required to affect lake levels..... 94, 115
Detroit River, effect of diversion compared with St. Clair River..... 142

Diversion, see "Chicago Diversion."

Elevation of a lake, meaning of term..... 90
Erie Canal, diversion through..... 111

Evaporation:

Effect of, on Great Lakes..... 91, 93, 114, 119, 128
Factors affecting 120, 122
Figures submitted, mean of 16 years..... 123
From Michigan-Huron Basin 114, 122

Exhibits, Complainant's:

No. 1. Discussed..... 95
No. 2. Discussed..... 106
Nos. 3 and 4. Discussed..... 102
Appendix FFF Report of Chief of Engineers, June, 1903, Discussed. 146-149, 151
Probable errors in gage readings..... 153-155

Gage readings, probable error in obtaining..... 153-155
"Governing Section":

Definition of term..... 133
Location of, between Lakes Huron and Erie..... 133

Ice:

Page

Effect of, in the St. Clair River on level of Lake Huron.....107, 109, 151
In St. Mary's River..... 108
Relation of, in St. Clair River to Chicago Diversion.....109, 110

Increment:

Definition of..... 113
Determination of..... 98
Form of expressing..... 98
For Niagara River with probable error..... 113
For St. Clair River with probable error.....113, 96
For St. Lawrence River with probable error..... 113
Value decreases towards St. Lawrence River..... 142
Value of, for St. Clair River.....97, 99, 137
Value of Niagara River..... 103

Lake Erie:

Effect of diversion at Chicago on.....90, 141
Effect of lowering on Lake St. Clair.....104, 105
Relation to level of Lake Michigan..... 142
Wind Storms, effect on..... 141

Lake Huron:

Effect of diversion at Chicago on.....90, 99, 100, 140
Effect of lowering on Lake St. Clair.....104, 105
Elevation compared to Lake Michigan..... 137
Evaporation from basin of.....114, 122
Flow of currents between Lake Michigan.....135-137
Ice in St. Clair River, effect on level of.....107, 109, 151
Relation to elevation of Lake Michigan.....90, 111, 133
Subterranean inflow and outflow of.....111, 121, 125-129

Lake Michigan:

Effect of Chicago diversion on.....90, 99, 140
Elevation compared to Lake Huron..... 137
Evaporation from basin of.....114, 122
Flow of currents between Lake Huron.....135-137
Range of elevation of..... 140
Relation to level of Lake Erie..... 142
Relation to level of Lake Huron,.....90, 111, 133
Subterranean inflow and outflow of.....111, 121, 125-129

Lakes Michigan-Huron: Page
Area of ... 116
Effect of Chicago diversion on storage capacity of ... 144-145
Evaporation from basin of ... 114, 122
Low water period ... 144
Precipitation in ... 124, 125
Subterranean inflow and outflow ... 111, 121, 125-129

Lake Ontario, effect of Chicago diversion on ... 90, 145

Lake St. Clair:
Effect of lowering Lake Erie on ... 104-105
Effect of lowering Lake Huron on ... 104-105

Lake Superior, depth of ... 121
"Lower," meaning of word ... 92
"Lowering," definition of term ... 91

Navigation:
Effect of lowering lake levels on ... 116
Financial loss to ship owners through lowering of lakes ... 118
Season of ... 106
Tonnage of freight carried on lakes ... 117

"Net Supply," definition of term ... 92

Niagara Falls:
Effect on Lake Erie by diversion at ... 103
Power at ... 114

Niagara River:
Fall of ... 114
Inconsistencies in outflow volume compared to St. Clair and St. Lawrence Rivers ... 112
Increment and probable error ... 113
Value of increment ... 103

Outflow, effect of, on Great Lakes ... 91, 93, 114, 119

Poe Locks:
Effect of change in slope of St. Mary's River on ... 134
Effect of lowering of lakes on ... 117
Facts concerning ... 134

Precipitation:
In Lakes' Basins ... 124, 125
Observations by Weather Bureau ... 93

Rainfall on Great Lakes ... 91, 93, 114, 119
"Relative elevation of the Lakes," Definition of term ... 89
Scouring in St. Clair River ... 110

	Page
St. Clair River:	
Changes in Cross Section	133
Degree of accuracy in discharge measurements	139
Effect of Chicago diversion on	90, 92, 100
Effect of diversion, compared to Detroit River	142
Ice effects on discharge of, on level of Lake Huron	107, 109, 151
Inconsistencies in outflow volume compared to Niagara and St. Lawrence Rivers	112
Increment and probable error for	96, 113
Location of "Governing Section" in	133
Location of meters in cross sections of	139
Measurements made in Summer seasons	108, 112
Number of meters used in measuring	138
Probable error of increment	96
Relation of ice in, to Chicago Diversion	109, 110
Scouring in	110
Value of increment	97, 99, 137
Width and depth of, at point of measuring	139
Wind storms, effect of, on flow through	108, 109
St. Lawrence River:	
Effect of Chicago Diversion on	106
Inconsistencies in outflow volume, compared to St. Clair and Niagara Rivers	112
Increment and probable error of	113
Increment of	106
St. Mary's River:	
Change in slope of, affecting Poe Locks	134
Effect of diversion on	101
Ice in	108
Subterranean Streams:	
Flow of	127, 129, 130
Flowing to and from Lakes Michigan and Huron	111, 121, 125-129
Source of	129-130
Vessels:	
Draft of, on Lakes	116
Factors limiting loading of	117
Size of, on Great Lakes	119
Welland Canal, Diversion through	111
Wheeler, Eben S.:	
Address	87
Education	87
Experience	87
Occupation	87
Wind Storms, Effect of, on Lake Erie	141

LOUIS C. SABIN'S TESTIMONY FOR COMPLAINANT.

Page
Direct examination 156-183
Cross-examination 183-194
Re-direct examination 194-197
Re-cross examination 197-198
Re-direct examination 198
Re-cross examination 198-199
Re-direct examination 199

Chicago Drainage Canal:
Effect of diversion on Lakes Michigan-Huron 165-178
Effect of diversion on St. Clair River 159

Discharge of Streams:
Length of time to determine vertical curves 189
Method of Measuring 157, 158

Diversion:
Effect of, on Lake Erie 172
Effect of, on Lakes Michigan-Huron 165-178
Effect of, on Lake Ontario 172
Effect of, on Niagara River 170, 172
Effect of, on St. Clair River 159, 170
Effect of, on St. Lawrence River 170, 172

Evaporation from Lakes Michigan-Huron 176, 177

Exhibits:
No. 1 Government's, discussed 164, 165
No. 2 Government's discussed 171
Pages 28, 30, 31, 32, 33, 34, 35, 36 and 37 of Appendix EEE of the Annual Report of Chief of Engineers for 1902, Introduction 186
Plate I opposite page 5400 of Appendix III, and KKK of the Annual Report of the Chief of Engineers for 1900, Introduced 187
"Statistical Report of Lake Commerce, 4-21-09," Introduced 182

Gages, Readings, precision of 198, 199

Gagings:
Effect of wind upon 196
Variation of Water Level at time of 190, 191

Government's Exhibits. See "Exhibits."

Ice, effect of, in St. Clair River 173

Increment:
Accuracy of computation for Lake Huron discharge 193, 194
Compensation of errors 195
Effect on, of drop of one or more feet of Lake Huron 191
St. Clair River 165
Wind, effect upon 192, 194, 196

Page

Lake Erie, effect of diversion upon 172

Lake Huron:

Accuracy of computations for increment 191
Effect on increment by drop of one or more feet 191

Lakes Michigan-Huron:

Conditions affecting level of 162
Effect of drainage canal diversion upon 165-178
Lowering of, effect on St. Mary's River and Poe Lock 167-169
Rainfall and Evaporation upon 176, 177

Lake Ontario, effect of diversion upon 172
Lake St. Clair, effect of diversion upon 169, 170
Lowering, definition of, by illustration of "Two Globes" 160, 161
Navigation, effect upon, of lowering lake levels 179-183, 185
Net Supply, definition of term 162
Niagara River, effect of diversion on 170, 172

Poe Lock:

Depth of Water 184
Effect upon, of lowering Michigan-Huron 167-169
Fluctuations of depth 184

Rainfall, upon Michigan-Huron 176, 177

Sabin, Louis C.:

Address 156
Experience 156
General 156-157
In hydraulics of Great Lakes 156, 157
Occupation 156

St. Clair River:

Accuracy of measurements in 189
Effect of Drainage Canal diversion upon 159
Effect of ice in 173
Increment of 165
Measurements of cross section and discharge of 188

St. Lawrence River, effect of diversion on 170, 172
St. Mary's River, effect of lowering Michigan-Huron upon 167-169
Vertical Curves, length of time to determine 189

WILLIAM LIVINGSTONE'S TESTIMONY FOR COMPLAINANT.

Page

Direct examination 200-200
Cross-examination 200-220
Re-direct examination 220-223
Re-cross examination 334
Re-cross examination 398-410
Re-direct examination 419, 420
Re-cross examination 420
Ballard's Reef, depth of water at 209
Boats. See "Vessels."
Channels, comparison of width and depth of, for navigation purposes 411-12

Cost of:
- Building vessels 214
- Cargoes per ton mile 221
- Operating vessels 213, 215, 217

Chicago River, navigation, dangers in 419-20
Currents in Great Lakes, swiftness of, to be called dangerous 410
Detroit River, interference with navigation by swiftness of currents in 409-10

Gilchrist Transportation Company:
- Information concerning 406
- Vessels owned by 406

Lake Carriers Association:
- Character of companies forming 404-5
- Number of vessels:
  - Affected by lowering of Lakes 398
  - Controlled by 203, 219
- Tonnage of vessels affected by lowering of Lakes 399
- Work of 410, 418

Lake Levels:
- Effect of lowering on carrying capacity of vessels 202, 204
- Effect on navigation by lowering of 413, 414
- Loss of revenue to shipowners due to lowering of 205, 218

Lake Michigan, effect on navigation by lowering of level of, two feet 413, 414
Lime Kiln Crossing, depth of water at 209

Livingstone, William:
- Address 200
- Experience 200
  - As vessel owner on Great Lakes 401-4
- Name 200
- Occupation 200, 402

Navigation: Page
Comparison of channel widths and depths for purposes of....411, 412
Cost of cargoes per ton mile.... 221
Difficulties in Chicago River....419-420
Effect on, by lowering of Lake Michigan two feet....413, 414
Interference on, by swiftness of currents in St. Clair and Detroit Rivers 409, 410
Length of season of.... 417
Loss of revenue due to low lake levels....205, 218
Swiftness of currents to be called dangerous to.... 410
Transportation problems of today.... 406

Pittsburg Steamship Company:
Ownership of....405, 408
Tons capacity of fleet.... 205
Vessels owned by....205, 406

Poe Locks, depth of water at....201, 209

Soo Locks:
Depth of water at Poe....201, 209
Size of new, under construction.... 222

St. Clair River, interference to navigation by swiftness of current of....409, 410

Tomlinson Company, G. A.:
Information concerning.... 406
Vessels owned by.... 406

Vessels:
Building of, for future traffic....207, 209, 210
Capacity of per inch of depth.... 203
Comparison of relative strengths of deep and shallow draft.... 222
Cost of building.... 214
Distribution of tonnage of, through different lakes.... 399
Effect of low lake levels on capacity of....202, 204

Expense of operating:
Accidents.... 217
Daily expenses.... 213
Depreciation.... 215
Insurance.... 213
Interest on investment.... 216
Factors governing size of commercial....201, 208
Increase in size of.... 211
Life of, on Great Lakes.... 214
Package freight, principal ownership of.... 407
Percentage of freight carried on lakes by largest.... 407
Time of expiration of insurance on.... 417
Volume of traffic and capacity of vessels compared.... 212

CHARLES KELLER'S TESTIMONY FOR COMPLAINANT.

	Page
Direct examination	224-251
Cross-examination	None
Bridge Section, see "International Bridge Section."	
Chicago Diversion:	
Effect of, on lake levels and connecting rivers	224
Lakes Michigan-Huron, effect on	229
Lake Ontario, effect on	233
Niagara River, effect on	249
St. Lawrence River, effect on	233
Current Meters:	
Description of	227
Operation of	227
Tests on, description of	250
Deep Waterways Commission, result of measurements on Niagara River, 1897, 1898	236
Diversion, see "Chicago Diversion."	
Erie Canal, amount of Diversion through	243
Exhibits, Complainant's:	
No. 1. Discussed	228
No. 2. Discussed	232
No. 3. Discussed	233
No. 4. Discussed	233
No. 5. Discussed	249
Ice, effects of:	
In St. Clair River on level of Great Lakes	240
On St. Clair River discharge	239-241
On St. Clair River increment	240
Increment:	
Algebraic equation expressing, for St. Clair River	228
Definition of	229
Determined by Quintas for Niagara River	237
Effect of ice on, in St. Clair River	240
Value of, for St. Lawrence River	233
International Bridge Section, more favorable than Open Section	235
Keller, Charles:	
Address	224
Education	244
Experience on Hydraulics of Great Lakes	224
Occupation	224, 247
Lakes Michigan-Huron, effect on, by Chicago Diversion	229
Lake Ontario, effect on, by Chicago diversion	233

Page

Lake St. Clair:
Equation giving level of ... 231
Accuracy of results of equation ... 232
Measurements of Streams, method of ... 226
Navigation:
Damage to vessels from lack of depth of water ... 247-249
Effect on, by lowering Lake levels ... 246
Net Supply, definition of term ... 225
Niagara River:
Accuracy of measurements, compared with St. Clair River ... 234
Effect of diversion at Chicago on ... 249
Effect of work on discharge of ... 243
Increments determined by Quintas ... 237
Reasons for taking two sections on ... 234
Results of measurements by Deep Waterways Commission, 1897-8 ... 236
Open Section less favorable for measuring than Bridge Section ... 235
Quintas, Increments determined by, for Niagara River ... 237
Sabin, Louis C., Ability as an engineer ... 245
Scouring, Change of regimen in St. Clair River ... 241
St. Clair River:
Accuracy of measurements, compared with Niagara River ... 234
Algebraic equation for increment ... 228
Character of men employed on measurements ... 245
Effect of ice in, on level of Great Lakes ... 240
Expenditures for measuring of ... 244
Ice, Effect of, on discharge ... 239-241
Increment, Effect of ice on ... 240
Scouring or change of regimen in ... 241
St. Lawrence River:
Effect on, by diversion at Chicago ... 233
Increment, value of ... 233
Welland Canal, amount of diversion through ... 243

SHERMAN MOORE'S TESTIMONY FOR COMPLAINANT.

Direct examination ... 252-266
Cross-examination ... 267-269
Re-direct examination ... 269-270
Re-cross examination ... 270-271
Re-direct examination ... 271-273

Chicago Diversion:
Effect on Lake Erie ... 265
Effect on Lakes Michigan-Huron ... 265
Effect on Lake Ontario ... 265
Effect on St. Clair River ... 265

Current Meters: Page
Causes of errors in Haskell....267-268, 271
Effect on, by passing boats....270, 271
Effect of weeds on operation of.... 269
Errors in Haskell....267, 271
Method of using.... 253
Rating of....260, 263, 272
Rejection of readings due to weeds.... 270
Results of tests....260, 261
Spinning tests on.... 272

Diversion. See "Chicago Diversion."
Erie Canal, measurement of flow in.... 264

Gages:
Location of recording, in St. Clair River.... 259
Recording, description of, used on St. Clair River.... 259

Gut Dam, effect of.... 256
Haskell Meters. See "Current Meters."

Increment:
Value of, for Niagara River....254, 265
Value of, for St. Clair River.... 260
Value of, for St. Lawrence River.... 257

International Bridge:
Changes in cross section at, from 1899 to 1907....254, 255
Measurements at.... 252
Method of making soundings at.... 255
Purpose of measurements at.... 252
Results of measurements at.... 254
Soundings at.... 254

Lake Erie, effect of Chicago diversion upon.... 265

Lakes Michigan-Huron:
Effect of Chicago diversion upon.... 265
Relation of level of, to outflow through St. Clair River.... 264

Lake Ontario, effect of Chicago diversion upon.... 265
Measurement of Streams, description of method of.... 253

Moore, Sherman:
Address.... 252
Education.... 253
Experience.... 252
Occupation.... 252

Niagara Falls, power developed at.... 266

Page

Niagara Falls Hydraulic Power & Mfg. Co., current meter measurements in canal of 261

Niagara Falls Power Company:
- Current meter measurements in canal of 261
- Weeds in canal of 268

Niagara River:
- Accuracy of measurements 262
- Accuracy of soundings 263
- Value of increment of 254, 265

Recording Gages. See "Gages."

Soundings:
- At International Bridge 254, 255
- Description of weight 255

St. Clair River:
- Accuracy of measurements in 262
- Accuracy of soundings in 263
- Dates on which measurements were made 270
- Description of recording gages used on 295
- Effect of diversion at Chicago 265
- Location of recording gages used on 295
- Measurements in 258
- Relation of level of Lakes Michigan-Huron to outflow through 264
- Securing in 263
- Value of increment of 260

St. Lawrence River:
- Accuracy of soundings 263
- Measurements in 256
- Value of increment 257

F. G. RAY'S TESTIMONY FOR COMPLAINANT.

Direct examination 273-280
Cross-examination 281, 282
Re-direct examination 282, 283

Critical areas:
- Definition of 273
- In Lake Erie 277
- In Lake Huron 276
- In Lake Michigan 274, 277
- In Lake St. Clair 276

Gage, self-registering, description of 278

Increment, value of, for St. Clair River 279

Page

Lake Erie:
Critical areas in ... 277
Relation of level of, to level of Lake Huron ... 279, 280

Lake Huron:
Critical areas in ... 276
Relation of level of, to level of Lake Erie ... 279, 280

Lake Levels:
Effect of, on navigation ... 280, 282
Effect of varying stages of water in Lakes Huron and Erie ... 279, 280
Lake Michigan, critical areas in ... 274, 277
Lake St. Clair, critical areas in ... 276
Navigation, effect of lower lake levels on ... 280-282
Ray, F. G.:
Address ... 273
Education ... 273
Experience ... 273
Occupation ... 273
St. Clair River, value of increment ... 279

F. C. SHENEHON'S TESTIMONY FOR COMPLAINANT.

Direct examination ... 283-322
Cross-examination ... 323-334
Cross-examination ... 335-398
Re-direct examination ... 420-425
Re-cross examination ... 425-427
Amhurstburg Gage ... 312
Areas, critical in navigation ... 321
Channels:
Effect of deepening ... 330, 424
Effect of docks on capacity of ... 331, 421
Effect of improvements on Lake levels ... 374
Chicago Diversion:
Lake Erie, effect ... 301, 378
Lake Huron, effect ... 296, 378
Lake Michigan, effect ... 296, 377
Lake Ontario, effect ... 307
St. Clair, effect ... 305
Niagara River, effect ... 304
General effect of ... 285
Cleveland Gage error ... 312
Coefficient work at International Bridge ... 299
Complainant's Exhibit, see "Government's Exhibits."

Curren Meter: Page

Accuracy compared with weir ... 338
Accuracy of multiple sets ... 340
Elimination of errors with multiple sets ... 352
Errors possible:
Due to weeds ... 366
Effect of oblique current ... 365
Maximum ... 366
Under registration ... 365, 366
Multiple meter sets ... 339
Tests ... 309, 310
Percentage of cross section covered by ... 340
Rating method ... 311

Data furnished Defendant's ... 291

Defendant's Exhibits:
"A" June 4, 1909, marked for identification "Chart of Detroit River." ... 335
"B" Discussed ... 342
Accuracy of ... 342
Identified, Plate 12 following Page 5400, Report Chief of Engineers, 1900 ... 341, 345
"C" Identified, Plate 7 following Page 5360, Report Chief of Engineers, 1900 ... 345
Discussed ... 345
"D" Identified, Plate following Page 5360, Report Chief of Engineers, 1900 ... 353
"E" Identified levels ...
"F" ...
"G" Superior, Michigan ... 354
"H" Huron, St. Clair, Erie ...
"I" and Ontario ...

Detroit River:
Accuracy of discharge measurements ... 388
Artificial changes in ... 421
Depths of ... 354
Livingstone Channel, effect on ... 323

Discharge measurements:
Accuracy of, in Detroit River ... 388
Object of ... 284
Precision of ... 308, 365
Rejection of, in 1901 ... 290

Diversion:
At Chicago (see Chicago Diversion.)
Length of time required to get effect of ... 298
Relation between, and "Net Supply" ... 287
Relation of fluctuations to ... 320

Page

Docks, effect on Channel capacity....332, 421, 422

Erie Canal:

Amount of diversion.... 376

Effect of diversion of Lakes.... 376

Evaporation:

Relation to lake elevations.... 378

Value of data....318, 319

Exhibits:

Complainant's..(See Government's Exhibits.)

Defendant's.....(See Defendant's Exhibits.)

Government's...(See Government's Exhibits.)

Fluctuations:

Huron-St. Clair....305, 368, 369, 393, 425

Relation to Diversion.... 320

Relation to Increments....360, 364, 371

Relative of Huron-Erie....305, 360, 363, 386

Gages, Water (see Water Gages.)

Government's Exhibits:

No. 1. Described....287, 289, 294

No. 2. Described.... 294

Nos. 3 and 4. Discussed....296, 300

No. 6. Introduced.... 310

Improvements, tendency of.... 328

Gut Dam, effect of....295, 307, 308, 332, 424

Harbor Beach Gage preferred to Milwaukee.... 357

Ice:

Discrepancies in lake levels attributed to.... 362

Niagara River, effect in....315, 316, 319

St. Clair River, effect in....315, 316, 319

St. Lawrence River, effect in....315, 316, 319

Relation of, to increment.... 316

Increment:

Definition of.... 290

Discharge line a curve.... 303

Error due to assuming, curve as straight line.... 303

Errors in (percentages)....314, 364

Fluctuations, relation to....360, 364, 371

Groups, method unfair, and fair....392, 394

Ice, relation to.... 316

Lake Erie Elevation, relation to Niagara River.... 370

Lake Erie, relative elevation relation to St. Clair River....382, 384, 386, 387

Lake Ontario, elevation relation to St. Lawrence River.... 370

Increment (Continued): Page
Lake St. Clair, neglected in St. Clair River....368, 390
Methods of obtaining, in St. Clair River.... 393
Niagara, International Bridge.... 304
Niagara, open section.... 302
Lake St. Clair, relation of, to St. Clair River....390, 391
St. Clair River, probable.... 297
St. Clair River, relation of, to Niagara River....361, 364

Improvements:
Effect of Channel, on Lake Levels.... 374
Tendency of Government's.... 329

International Bridge:
Check with Open Section....301, 302
Co-efficient work at....299, 300
Cross sectional area of section.... 353
Increments.... 304
Measurements described....298, 299
Soundings at.... 299
Verticals in section....352, 353

Lake Erie:
Change of elevation in relation to Huron between periods, 356, 358, 373, 375, 423
Effect of Chicago diversion on....301, 376
Effect of Niagara Falls Diversion on....318, 333
Relative Fluctuations of Huron-Erie....305, 360, 363, 388

Lake Huron:
Change of elevation in relation to Erie....356, 358, 373, 375, 423
Effect of Chicago Diversion on....296, 285, 377
Fluctuations of Huron-St. Clair....305, 368, 369, 393, 426
Percent of lowering at Poe Locks.... 297

Lake Levels:
Changes in relation of Huron and Erie between periods.356, 358, 373, 375, 423
Discrepancies in, due to rainfall and ice.... 363
Elevations, comparison of periods....423, 427
Effect of channel improvements on.... 374
Effect of deforestation on.... 424
Effect of rising, on Niagara discharge.... 384

Influences Affecting:
Chicago Sanitary Canal....376, 377
Erie Canal Diversion.... 376
Lake Superior Impounding....378, 380
Welland Canal Diversion.... 376

Lake Michigan, effect of Chicago diversion on....296, 377

Lake Ontario, effect of Chicago diversion on.... 307

Page

Lake St. Clair:
- Effect of Chicago Diversion on 305
- Effect of Livingstone Channel on 324

Lime Kiln Channel, dimensions of 336

Livingstone Channel:
- Dimensions of 337
- Effect on Detroit River 323
- Effect on Lake St. Clair 324
- Nature and dimensions 323, 336, 337

"Lowering," meaning of word 286

Meters. See "Current Meters."

Milwaukee Gage, reliability of 355, 357

Neebish Channel:
- Effect on level of water 325, 328
- Nature and dimensions 325

"Net Supply":
- Meaning of term 286
- Relation between diversion and 287

Niagara Falls:
- Effect of diversion at, on Lake Erie 317, 333
- Power per cubic foot of water 314, 333

Niagara River:
- Artificial changes in 420, 421
- Effect of Chicago diversion on 304
- Effect of ice in 315, 316, 319
- Effect of rising lake on discharge of 364
- Relation of St. Clair River Increment to 361, 364
- Transverse velocity curves taken on 350

Observations:
- Relation of number to accuracy of result 313
- Year 1901, rejected 290

Open Section:
- Check with International Bridge 301, 302
- Cross sectional area 353
- Increment 302
- Location of 301
- Number of verticals in 352

Poe Lock, percent of Huron lowering, felt at 297

Rainfall:
- Discrepancies attributed to 382
- Relation of, to lake elevations 378
- Value of data 319
- Wheeler's observations introduced 396

Page

Scouring, in St. Clair River 317

Shenehon, Francis C.:
- Address 283
- Experience 283
- Occupation 283

Soundings:
- At International Bridge 299
- Precision of 311

St. Clair River:
- Error in discharge observations 306
- Ice effects in 315, 316, 319
- Increment neglected with Lake St. Clair 368, 643
- Increment, possible method of determining 368
- Probable increment 297
- Relation of, Niagara River increment 361, 364
- Relation of, to Lake St. Clair increment 360
- Scouring in 317

St. Lawrence River:
- Cross Sectional Area 353
- Ice effects in 315, 316, 319
- Measurements 306
- Number of verticals on 352, 353
- Slope of 370, 371

St. Mary's River:
- Changes in slope of 327
- Dangerous currents in 436
- Effect of locks on 327

Subterranean outlets of lakes 315

Velocity:
- Coefficients:
  - Meaning of 343
  - Values of 349
- Curves:
  - Transverse, relation to coefficients 350, 351
  - Transverse, taken on Niagara work 350
  - Transverse, use of 350
- Uniformity of, in flowing streams 338, 343

Verticals:
- Number of, in bridge section, Niagara River 352, 353
- Number of, in open section, Niagara River 352, 353
- Number of on St. Lawrence River 353

Water Gages: Page
Changes at Milwaukee....312, 355
Precision of....312, 355
Relations between.... 292
Water measurements, accuracy of methods....337, 338
Welland Canal:
Amount of diversion.... 374
Effect on lakes....374, 376
Influence of diversion on lake levels.... 376

HARRY COULBY'S TESTIMONY FOR COMPLAINANT.

Direct examination 428-432
Cross-examination 433-445
Ballard's Reef, depth of, loading for vessels passing.... 429
Cleveland harbors, depth of.... 437
Coulby, Harry:
Address.... 428
Experience.... 428
Name.... 428
Occupation.... 428
Harbors, effect on, by lowering of lakes.... 432
Lake Carriers Association, activities of in improving navigation.... 443
Navigation:
Cost per ton for carrying ore....431, 441, 443
Number of days to average season.... 440
Total tons of freight carried per year on Great Lakes.... 436
Pittsburg Steamship Company:
Company's vessels as common carriers.... 435
Cost per ton for carrying ore....431, 441, 443
Dimensions of ships operated by.... 430
Effect on season's operation of vessels by lowering of lakes.... 432
Nature of cargoes carried by.... 428
Number of vessels operated by....429, 435
Percentage of business to and from Lake Superior....428, 433
Stock in, controlled by.... 434
Tons of freight carried in vessels chartered by.... 435
Tons of freight carried in largest vessels operated by....429, 433, 439
Poe Locks, depth of loading for vessels passing....429, 433, 439
Vessels:
Capacity of, per inch of draft.... 430
Charge for interest and depreciation on.... 441
Danger in operating, in currents of Great Lakes.... 437

Vessels (Continued): Page
Depth of loading of, for passing Ballard's Reef 429
Depth of loading of, for passing Poe Locks 429, 433, 439
Draft of, built in recent years 436
Number of trips made per year 430, 440, 441
Operating expenses of:
For larger vessels 440
Not fully loaded 430
Per year 441, 443

ALLEN HAZEN'S TESTIMONY FOR DEFENDANT.

Direct examination 445-461
Cross-examination 461-481
Re-direct examination 481, 482
Re-cross examination 482
Calumet District:
Population of 472
Works for 453
Calumet Sag Canal, effect of, on water pollution 454
Drainage Canal, inspection of 449
Hazen, Allen:
Chicago problems, acquaintance with 447-449
Education 445-446, 465
Experience:
On Lawrence Experiment Station 445, 461
On World's Fair Plan 446-462, 3, 4
Occupation 445
Partners 446-7
Plants connected with 446-7
St. Louis vs. Sanitary District, connection with case 469
Sewage Disposal (General):
Cost of, different systems 450
Difficulties encountered in 450
European problems of, compared with American 450-1
Intermitten Filtration:
Altoona, Pa., Plant 465-6
Paterson, N. J., Plant 468
Plainfield Plant 466
Pittsburg Plant 466-7-8
Spencer Plant 466
London Plant 470
Methods of 473, 478

European practice 555
General opinion on purification of 550
Lake population, effect on 553, 555, 556
Relation of, to Sewage Purification 556

VOL. II.

CLASSIFIED TABLE OF CONTENTS.

GARDNER S. WILLIAMS' TESTIMONY FOR DEFENDANT. Page

Direct examination 566-744
Cross-examination 744-982
Re-direct examination 983-989
Re-cross examination 989-990
Asiatic Cholera 761, 765
Anthrax 762

Barometric Pressure:

Effect on Lake Erie 839
On Niagara 839
Possible maximum 840
St. Clair River 840
St. Lawrence River 840
Factor, not important .....

Blanchard, Murray:

Measurements of:
Detroit River 709, 752, 793
St. Clair River 793
St. Lawrence River 793, 794, 796

Boats:

Courses:
Of travel .....
Meaning of term 590
Passenger, draft of 597
Passing, effect of 591
Stranding of, at Grosse Point 774, 778, 835
Buffalo Harbor, Chart of 955
601

Channels:

Controlling points in 605
12-foot, of 1858 699
13-foot, of 1867-71 699
16-foot, 1871-74 700
20-foot, 1893-96 700
Grosse Point, 1893-97 700
Improvements in, government 701
Lime Kiln, 1876-91 ..... 604, 605
Livingstone, 1908-12, description 700
701, 702

Material Removed from:

Page

Effect of, U. S. Engineers 704
By government 605, 698, 704
By private parties 699
Profile of 727
North and middle, restriction of 743
Stony Island, discharge of 717, 727
Trenton, discharge of 717, 727
Width at St. Clair Flats 596

Chicago Drainage Canal:

Compared with canal at Cornell 772
Cross section of 727
Date of opening 739
Microscopic size on chart 954
Performed anticipated purpose 986
Propriety of Niagara increment applied to diversion, effect of 988
Coefficients in government equations, correctness of 934

Compensation:

Effect of gut dam in 743
Interference with navigation 757
Method and cost of 743
Reducing Channel Discharge:
St. Clair 743
Stony Island 743
Trenton 743

Cornell:

Canal, compared with Chicago Drainage Canal 772
Hydraulic Laboratory, description of 772
Schoder's work at 736
Weir at 509
Williams, G. S., Professor at 567

Cross Sections:

Chicago Drainage Canal 727
Niagara River 727
St. Clair River 727
St. Lawrence River 727

Current Meter:

Page

Action in eddies....734, 958
Applicability in general.... 783
Agreement of Price and Haskell.... 909
Cup Meter, Limit of over-registration of.... 958

Ritchie-Haskell.... 570
In St. Clair work.... 735
Discrepances of.... 737
Floats compared with....776, 783, 785, 788
Fluctuations of, diurnal.... 908
Haskell, described.... 733

Rating:

By coloring matter....911, 913
At Cornell.... 731
At Detroit water works.... 770
Errors in....913, 963
Of Vogleson, J. A.... 732
Screw meter distinguished from cup meter.... 957
Tests of.... 730

Use:

On small streams.... 782
In Wilmette pump test....788, 792
Weirs, compared with, at Cornell....730, 788
Williams, G. S., experience with at Cornell....730, 771

Detroit River:

Agreement with St. Clair....712, 715, 719
Agreement with St. Lawrence.... 730
Chart of....598, 599

Discharge of Channels:

Lime Kiln....717, 727
Livingstone....717, 727
Stony Island....717, 727
Trenton....717, 727
Dredging, effect on....754, 807, 916

Affected by:

Livingstone Channel....716, 719
Lakes St. Clair and Erie.... 709
Elevations at Amherstburg.... 618
Flow in, reversal of.... 580

Increment: Pa
Method of deriving 7
Values of 710, 713, 7
Adopted by G. S. Williams 7
Least squares, method of, applied to 7
Measurements 574, 7
By Murray Blanchard 709, 752, 7
Record of 7
Reference plane 5
Shallowest place in 6
Width of 5

Discharge:
Change of elevation, expressed as 9

Detroit River:
Compared with St. Clair 711, 7
Obstructions to 714, 7
Dredging, effect on 9
Fluctuations, relation to 8
Gauge reading, relation to 6
Great Lakes, rivers of 724, 574, 6
Increment, relation to 590, 736, 738, 8

Law of:
For Great Lakes, not established 8
For Niagara River, impossible to derive 8
Of Lime Kiln Channel 717, 7
Of Livingstone Channel 7

Measurements:
U. S. L. S. for St. Clair 616, 6
Of Niagara 610, 8
Summary of 6
Of St. Lawrence River, summary of 6
Of Lake Ontario 6
Of St. Clair River 573, 609, 620, 664, 6
Of St. Lawrence, 1900-04 6
Of Stony Island Channel 717, 727, 7
Of Lake Superior 6
Tilting of Lake, effect on 891, 9

Diversion, Effect of:
Detection of, 10,000 c. f. s. not possible 6
Engineers, Error of 7
Lake Erie, 10,000 c. f. s. on 742, 749, 7
Haskell's study of 7
Lake Huron-Michigan, 10,000 c. f. s. on 742, 748, 7

International Waterways Commission Report:
Page
According to increments of 804
On Lake Erie 674
Error in 754
Lake Ontario, 10,000 c. f. s. on 742, 747

Dredging:
Discharge increased as result of 930
Effect of, in St. Clair and Detroit Rivers 754, 807, 916
By government 605, 698, 704, 699–702
Lime Kiln most effective 953, 954
Lowering, due to 928

Material:
Disposition of 916
Disposition considered in computations 917
By private parties 699
Time distribution of, J. R. Freeman 952

Elevation, Change of:
Expressed in volume of discharge 929
Most rapid in 1889–90 931
Engineers who have studied effect of diversion 752

Equations of Discharge:
Niagara River from Erie 948
St. Clair from Huron 639

Equations of Elevation:
Applicability of 935, 936
Correctness of, coefficients of 934
Erie from Huron 933
Erie from Ontario 933
Huron from Erie 933
Ontario from Erie 933
St. Clair-Huron fluctuations 944, 949
St. Clair from Huron 944

Erie Canal, diversion of water through 681

Erie, Lake:
Chart of 601
Detroit River, influence on 710
Discharge of tributary rivers 679

Diversion of 10,000 c. f. s., effect of:
I. W. W. C. 749
Shenehon 749
G. S. Williams 750

Elevation:
Computed from Lake Huron
Computed from Lake Ontario
Observed and computed
Evaporation
Amount
More than rainfall
Fluctuations of 648, 667, 669, 672, 706, 723, 81
Lake levels, change of during measurements 84
Levels:
Buffalo, hourly, June-August, 1908 (table)
Computed
Rainfall on 690, 723, 73
Regulation of
Regulation of, to St. Clair and Huron
Run-off, local 677, 67
Stability of, during observations 85
Stage, mean of, 1860-69, compared with Huron

Evaporation:
Affected by clearing of lands
On Lake Erie:
Computed 68
More than rainfall
General statements 58
On Great Lakes
Summary of
Inconsistency, on Lake Erie
On Lake Ontario, computed
Relation to rainfall 58
Records of, at Rochester

Exhibits, Complainant's:
"A," Observed and computed lake elevations 93
"A," discussed
"B," Relative fluctuations, Huron-St. Clair 94
Chart No. 6, general, of Great Lakes
Government's:
"C," Report of Oakfield and Wickwire gauging
"D," Still water rating, smelting works base
"E," Niagara discharge plotted against Buffalo gauge
"F," Hourly plottings, Lake Erie levels, Niagara discharge
"G," "H," "I," "J," "K," "L," Hourly plottings, Lake Erie levels, Niagara discharge
"K," Discussed
Haskell's No. 1, discussed

Fluctuations:
Definition of ..... Page
Equation of, St. Clair-Huron 870
Of Lake Erie due to wind 944
Erie-Ontario 672
Of Gages: 667, 668
Between Buffalo and Chippewa 868
Between Buffalo and Cleveland 869
Between Cleveland and Chippewa 871
Of Huron-Erie 648, 668, 706
Ratio of 827
Of Lake Huron by Government's Exhibit "B" 949
Laws of, Complainant's not accurate 950
Line of:
Applicability of 818
Curvature of 819
Local supply, no influence on 820
Monthly, not used in determining increment 706
Precision in, limits of 821
Rainfall and evaporation, not applied to 820
Relation:
To increment 588, 666
To increment (Shenehon) 671
To discharge measurements 864
Of St. Clair-Erie 723
Of St. Clair-Huron 648
Broken line representation 950, 951
Relative 943, 952
Three Point method, application of 668
Freeman, J. R.:
Exhibit No. 1 952
On Ice 978
Gages:
Amherstburg 599, 840
Buffalo:
Compared with Cleveland 885, 887
Computed from Chippewa 898
Fluctuations of 868
Hourly readings 861, 897
Instability of 837
Not mean of lake 672
Plottings of 729
Recording gage established 902
Variations, daily 862
Variation during 107 observations 865

Pag

Canadian opposite Buffalo 84

Chippewa:
- Actual compared with computed 8
- Computed from Cleveland 8
- Errors of, computed 8
- Fluctuations of 868, 869, 87
- Hourly readings, November, 1906 8
- Prediction of, from Buffalo 8
- Relation to Niagara discharge 892, 8

Cleveland:
- Fluctuations of 869, 87
- Mean of lake 67
- Plottings 72

Difference, maximum, Buffalo-Amherstburg 84
Grand Trunk location 62

Harbor Beach:
- Care in reading 658, 72
- Derived 62
- Location of 62
- Plottings of 72

Mamajuda Light 60

Ogdensburg:
- Distance from Lake Ontario 604, 62
- Plottings of 72

Oswego:
- Location 60
- Plottings of 72

Trouble with:
- At Buffalo 83
- On Lake St. Clair 83

Gagings:
- Agreement of, St. Lawrence, St. Clair and Detroit 73
- Chronological grouping of 66
- Current meter method, accuracy of 98
- Difficulties with large rivers 612, 77
- Errors in 910, 91
- Factors entering into accuracy of 730, 951, 959, 962, 96
- Method of making 611, 61
- Precision of river (Shenehon) 65
- Of St. Mary's River 77
- Time required at dry dock 62

Elevations:
Computed 924, 933, 935
Daily 618
During discharge measurements 643, 644
Mean 641, 642
Monthly 618
Evaporation computed 684
Fluctuations of 648, 649, 699, 706, 827, 949
Relative to St. Clair 943, 949, 950, 952
Relative to Erie 649
Formula expressing relation of, to Erie, discussion of 927
Gauges (see "Gauges"), lowering of, total 1.43 feet 689
Rainfall on 689, 723, 725
Run-off, local 678, 724
Stage, mean, 1860–1889, compared with Erie 668

Hydraulics:
Definition 607
Distinguished from Hydrography 607
Of the Great Lakes 674
Williams, Gardner S., Experience 506, 567

Hydograph of lake elevations 926

Ice:
Conditions of Niagara 980
Conditions of Lake St. Clair 980
Effects:
On lake levels 933
Not considered in G. S. W. computations 979
Shown by complainant 937, 938
In St. Clair River (J. R. Freeman) 978
Examined into, by Gardner S. Williams 982
Importance of, (J. R. Freeman) 979
Report of Chief of Engineers on 980

Increment:
Agreement with complainant on Lake St. Clair 649
Based on Huron, most accurate 643
Definition of 587
Dependent on slope and cross section 824
Determination of, Gardner S. Williams 636

Page

Of Detroit River:
- Derivations, method of 709-711
- Equation of 712
- Erie alone (17,290) 709
- Probable (32,000) 712
- St. Clair alone (45,380) 710
- St. Clair net (28,850) 710
- Value of 710, 713-714

Error:
- Adopted 914
- Most probable maximum 741

Of Lake Huron:
- Corrected (31,370) 66⅔%, 1890-1902 ..... 655, 657
- Corrected (28,758) 89%, 1908-9-10 ..... 931, 657, 658
- Corrected (30,579) 66⅔%, 1908-9-10 ..... 660, 662
- Corrected (27,938) 89%, 1908-9-10 ..... 657, 658
- Net (27,517) 66⅔%, 1890-1902 649
- Net (24,613) 89%, 1890-1902 650
- Net (27,919) 66⅔%, 1908-9-10 660
- Net (25,280) 89%, 1908-9-10 660
- St. Clair constant (34,385) 646

Of lakes, greater at higher stages 805, 807

Line of, straight for investigation purposes 875

Most probable as submitted by G. S. Williams:
- Detroit River (32,000) 740
- Niagara River (34,000) 740
- St. Clair River (29,000) 740
- St. Lawrence River (30,500) 740

Necessity of determining 588

Of Niagara River:
- Based on complainants' exhibits (F-1) (45944) 966
- Based on mean of Amherstburg & Buffalo 841
- Buffalo Gage (26155) 672, 673
- Buffalo and Amherstburg Gage (33142) 672

Complainants:
- Bridge section (21,900) 671
- Open section (21,640) 671
- Cleveland Gage (30,460) 672
- Cleveland Gage, corrected (32,307) 672
- Defendant's deduced (35,000) 671

Derivations: Page

From I. W. W. Report ... 673
From Ft. Clair ... 821
From two observations (53,000) ... 856
From two periods ... 889
From St. Lawrence (35,480) ... 668, 669
Effect of 10% error in observation ... 890

Rainfall:
- Data furnished to Shenehon 1083, 1089, 1112
- Error, relation to Stearns' deductions 1109
- On Lake Ontario, 1900–1904 1020
- "Rainfall and Runoff," by George W. Rafter 1114
- Records of:
  - Accuracy of 1115, 1124
  - On Great Lakes 1003
    - Map showing location of stations 1003
    - Period of years covered by records 1003
- Relation to runoff 999
- Stearns, F. P., experience with data of 993
- On St. Clair-Erie, 1900–1904 1020
- Volunteer observers of 1111, 1123

Report, of Hering, Williams & Arstingstall 1065

Rivers:
- Discharging into brackish water, cities on 1061
- Discharging into fresh water, cities on 1061
- Of Great Lakes, inconsistencies among 1138
- Large, difficulties in measuring 1024

Runoff:
- Changes of 1101
- Data furnished to Shenehon 1083, 1089
- Deductive, reliability of 1120
- Effect of forestation on 1116
- Of Huron River 1119
- Of Lake Erie, Ontario, percent rainfall 1011, 1021, 1116, 1122
- Of Maumee River 1116
- Of Lake Ontario 1022, 1122, 1123
- Percent assumed 1007
- Precipitous ground, effect on 1125
- Rafter, George W., on 1132
- Records of, accuracy of 1115, 1123
- Relation to lake elevations 1134
- Relation to rainfall 999, 1132
- Of Sandusky River 1119
- Of streams, Stearns' method of deriving 1123
- Of Wachusett Drainage, method of obtaining 1000

Screening or Sedimentation:
- Discussed 1048
- Would reduce necessary dilution 1071

Settling Tanks:
- Reduce necessary dilution 1071

Sewage Disposal:

CLASSIFIED TABLE OF CONTENTS.

JOHN R. FREEMAN'S TESTIMONY FOR DEFENDANT.

Page

Direct examination 1145-1195

Cross-examination 1195-1236

Re-direct examination 1236-1237

Re-cross examination 1237-1239

Re-direct examination 1239

Bridge Section:

- Discrepancies in discharge of 1187
- Disturbance of River at 1184-1186
- Inherent errors of 1208

Compensation:

- Cost 1173, 1175
- Interference with Navigation 1173, 1174
- Method of 1172, 1174
- On Lake Erie 1173
- On Lake Ontario 1173
- On Lake Superior 1173

Correction:

- Time correction of G. S. Williams' Method 1201
- Williams', G. S., Tables Corrected 1236

Criticism of U. S. L. S. gagings 1178, 1179

Current Meter:

- As chief source of error in Niagara observations 1204, 1205
- Effect on, of disturbed water 1182, 1185
- Rating by coloring matter 1185

Discharge:

- Effect of ice on 1156
- Comparison of, Niagara River and St. Clair River 1178, 1187

Diversion Effects:

- Detection from levels impossible 1150, 1187, 1188
- Detection from physical measurement impossible 1188

Dredging:

- Effect of, on discharge 1211
- Effect on Lakes Huron and Michigan 1170, 1237
- Influence of lime kiln compared with head of St. Clair 1210, 1214, 1237, 1238
- Magnitude of 1171

Page

Error:
Current meter as chief source of in Niagara observations 1205
In gagings 1188
Inherent errors of Niagara Bridge section 1208
Sources of, in gage readings 1162
Oakfield section, possible error 1209
Wickwire section, possible error 1208, 1209

Evaporation:
Lake Erie 1179, 1230
Rochester records 1180, 1181
Salton sea records 1180

Exhibits:
Complainants, F, G, H & I, discussed 1219
Complainants L:
Reference to 1200
Comments on 1201–1203

J. R. Freeman's:
No. 1 "Studies relative to Chicago Drainage Canal" 1153, 1160, 1171, 1173
No. 2 Introduced 1163
No. 3 Introduced 1167
No. 4 Introduced 1183
No. 5-9 (inclusive), introduced 1189
Government's M introduced and discussed 1207

Fluctuation, Causes of:
Barometric changes 1161
Clogging of outlets by ice 1153–1160
Effect not apparent in Government tabulations 1162
Rainfall 1153
Spring floods (season rise) 1161
Wave effects 1162
Wind 1161

Freeman, John R.:
Address 1146
Business 1146
Experience 1146, 1180
First hand knowledge of Niagara River 1231
School 1146

Gage:
Buffalo, range of 1161
Sources of error in reading 1162

Page

Gagings:
- Accuracy of line drawn by eye in Niagara ... 1203
- Criticism of U. S. L. S. ... 1178
- Discrepancies between successive ... 1187
- Errors in ... 1186, 1188
- Messena, N. Y., at ... 1181, 1182
- Weight to be given third gaging ... 1205, 1206, 1208, 1231, 1232

Groat, B. F., Credibility of work ... 1183

Gut Dam:
- Effect of ... 1172, 1173
- Effect on regimen of St. Lawrence ... 1224, 1225

Ice:
- Cover, kinds of, defined ... 1154, 1155
- Effects of ... 1207, 1226
- Effect on discharge ... 1156, 1157
- Fluctuations of lakes by clogging outlets ... 1153
  - Mississippi ... 1155, 1156
  - Niagara ... 1155
  - St. Clair ... 1155
  - St. Lawrence ... 1155, 1156, 1158
- Frazil ... 1158
- Gorge, kinds of, defined ... 1155
- Slush ... 1159

Increment:
- Accuracy of, from line drawn by eye ... 1204
- Accuracy of, affected by range of elevations ... 1221

Lake Erie:
- Evaporation ... 1179, 1230
- Local supply ... 1179, 1180
- Run-off ... 1227, 1233

Lake Huron:
- Lowered by channel deepening ... 1170–1172, 1212, 1226, 1237
- Lowered by ice gorge ... 1238
- Range ... 1165

Lake levels, benefit of lower ... 1175, 1176

Methods of Computation:
- Comparison of Three Point with least squares and string ... 1195, 1196
- Contrast between G. S. Williams' and government method ... 1149–1198
  - Lake St. Clair, relation to St. Clair River increment ... 1140
  - Three Point vs. String ... 1149
  - Use of selected observations ... 1150
- G. S. Williams', of:
  - Comments on, J. R. Freeman ... 1165, 1198, 1217, 1228–1231
  - Extent of Freeman check ... 1190, 1200
  - Time correction ... 1201

Page

Niagara River:
Description of portion of 1183–1185
Discharge compared with St. Clair River discharge 1178, 1180, 1186
Discrepancies between successive measurements 1187
Ice effects 1155
Rejecting observations, reason for 1206, 1229, 1232, 1239

Outlets:
Of Great Lakes, condition of 1186
Scouring of 1166

River Regimen:
Change of, St. Clair River 1226, 1234
Effect of Gut Dam on, St. Lawrence River 1224, 1225

Sanitary Canal:
Cost of 1176, 1177
Designed for navigation 1177

St. Clair River:
Change of regimen 1226, 1234
Discharge compared with Niagara River 1178, 1179, 1187
Ice effects 1155–1160

St. Lawrence River:
Gut Dam, effect on regimen 1224, 1225
Ice effects 1155, 1156, 1158

Testimony:
Study Given:
Of F. C. Shenehon 1148
Of G. S. Williams 1148, 1227

Water supply, importance of not polluting 1195

Williams, G. S.:
Methods:
Extent of Freeman check 1199, 1200, 1234
Comments on, by Freeman 1198, 1217, 1228, 1231
Contrast with government methods 1149, 1150
Tables corrected 1236, 1237

Wind, effect on fluctuations of lake levels 1161

HERBERT C. SADLER'S TESTIMONY FOR DEFENDANT.

Page

Direct examination 1240-1252
Cross-examination 1253-1269
Re-direct examination 1269-1277

Biles, Professor Sadler's connection 1269

Boats:
- Classes of (types) 1244, 1245
- Cost of changing proportions 1248
- Depth of, defined 1246
- Draft of, defined 1246
- Draft of, Great Lakes 1244
- Five hundred foot class 1248, 1253
- Four hundred foot class 1247, 1271, 1273
- Freeboard, defined 1247
- Freight, percentage carried by 1246
- Handling, in shallow water 1266
- Number on Great Lakes 1244, 1261
- Ocean 1263
- Ore, out of service 1271
- Ore, ownership of 1272
- Rail vs. Boats 1276, 1277
- Resistance to water 1258, 1259
- Six hundred foot class 1253, 1254, 1271, 1272
- Sizes of, on Great Lakes 1244
- Stability 1259
- Tonnage of, defined 1246
- Welland Canal type 1242, 1243, 1255

Cole, designed by Sadler 1252

Cost:
- Of carrying cargo 1268
- Of handling cargo 1259, 1260
- Total to change all boats 1248

Draft:
- Maximum possible 1251, 1252
- Possibility of 24 feet 1256, 1273
- Soo fixes present 1255, 1256

Estimates:
- Basis of Sadler's 1271
- Method of computing 1257, 1258
- Of changing boats 1248

	Page
Freight Rates, Factors Affecting:	
Boats returning empty	1273
Boats returning loaded	1263
Effect of larger boats	1274, 1275
Number of boats	1261
Great Lakes:	
Engineering company business	1242
Boats, sizes and number	1243, 1244
Boats, types	1244, 1245
Traffic	1243
Length, Increase of:	
Due to loss of draft	1245, 1256, 1257
Methods of computing	1257, 1258
Loss:	
Dependent on number of boats	1261
From 6 to 10 inches	1264
On basis of future business	1274, 1275
Per year to commerce	1240
Speculation on future business	1275, 1276
Total	1251
Naval tank, description	1242
Present Tendencies:	
Commerce increasing	1262
Freight rates decreasing	1274
Lumber supply becoming exhausted	1276
Ore supply becoming exhausted	1275
Size of vessels	1254, 1255
Sadler, Herbert C.:	
Business	1240
Education	1240
Experience	1240, 1241, 1267, 1270

Relation of Detroit to Soo	1266

JOSEPH RIPLEY'S TESTIMONY FOR DEFENDANT. Page

Direct examination 1277-1316
Direct examination 1323-1324
Cross-examination 1316-1323
Cross-examination 1324-1352
Re-direct examination 1352-1353

Advisory engineer, Ripley to New York State 1284
Alabama survey 1284
Barge canal 1325
Bixby, Major W. H 1288
Black Warrior River 1284
Blunt, storm conditions on Lake Erie 1334

Channel Improvements:
Detroit River 1294, 1304, 1346
East Neebish 1279
Familiarity of Ripley 1280, 1281
Hay Lake 1279, 1280
Lake Erie 1596
Lake George 1279
Lake St. Clair 1303
Little Mud Lake 1279, 1280
Methods of Making 1295, 1298, 1299
Middle Neebish 1280, 1336-1338
Poe Reef 1313
St. Lawrence 1340, 1341
Sault Ste. Marie 1279
Sleeping Bear Point 1313
Under 1903 project 1280
West Neebish 1280

Cleveland Gage 1320

Compensating Works:
Cost of 1310, 1311, 1338, 1339
Effect on currents 1312, 1313
Increased depth by 1312
Nature of 1311
St. Lawrence River 1338

Consulting engineer to New York State engineer 1284

Cost (see "Estimates of Cost").

Critical Points:
In St. Mary's River 1305
Mitre Sill Poe Lock 1305
Off Thunder Bay 1313

Page

Currents, relation to regulating works 1312

Dam:
- Gut, effect of 1328
- In middle Neebish 1336, 1338
- In St. Clair River 1337

Davis:
- General George, Chairman Panama Canal Board 1282
- Col. Chas. E. L. B. Charge Detroit District 1288
- Lock, platform in 1353
- Lock, depth provided 1305

Detour gage 1289

Detroit:
- District of 1288
- River improvements 1294, 1304
- River, cost of deepening 1346–1348

Estimate of Cost:
- Compensating works 1310, 1312, 1338
- Deepening canals 1307
- Deepening channels 1306, 1321
- Deepening Detroit River 1346
- Deepening harbors 1350
- Explanation of 1341, 1345
- Harbors included in 1316
- I. W. W. Commission 1308, 1321, 1348
- Lake Erie 1349, 1350
- Project of 1903 1336
- Regulating St. Lawrence 1338, 1339
- Removing platform Poe Lock 1305
- Ripley's familiarity with 1280, 1281
- St. Mary's and Panama 1285
- Soundings, basis of 1310
- St. Lawrence canals 1322, 1323
- Time spent in preparing 1343
- U. S. Government 1285, 1344, 1347

Farquardt, Major F. W 1288

Farrans Point:
- Excavation necessary 1340
- Fall at 1340

Chicago Drainage Canal:
- Changes accomplished by 1417, 1421, 1429
- Cost of present (Table) 1458
- Diversion, amount of, present 1481
- Lag of water in 1478, 1479
- Oxygen necessary in canal 1499
- Purpose 1417
- Reduction of flow in canal to 4167 c. f. s.:
  - Effects of 1429–31, 1495, 1496, 1497
  - Remedial measures 1431
- Sludge deposits in 1514
- Report of Rudolph Hering on, 1907 1464

Chicago River:
- Discharge of 1476
- Present diversion, amount of 1481
- Effect of lake levels on 1512
- Water to reverse flow, amount of 1479, 1481

Chicago Sanitary District:
- Description of works of 1416
- Report to by Hering, 1907 1464

Chicago Situation:
- Description of, 1889–1900 1413
- Fuller's familiarity with 1412

Condemnation of land 1444, 1446
Construction, time required for 1444
Contact Beds, general description 1426, 1456

Cost:
- Aerating devices 1447, 1450
- Aeration compared with sprinkling filters 1495
- Attendance (Project A) 1452
- Depreciation (Project A) 1450
- Intercepting sewers 1447
- Land 1449
- Metering Chicago water 1511
- Operation and maintenance (Project A) 1450–1452
- Operation, Total (Project A) 1452
- Operation, Total (Project B) 1454, 1455
- Operation does not include present canal 1457, 1458
- Overhead 1448, 1450, 1455
- Present canal (Table) 1458
- Project A itemised 1450
- Pumping station 1447, 1449–1451
- Sedimentation tanks 1448, 1450

Page

Cost—Continued:
Separate system of sewers (Project B) 1452
Sprinkling filters 1448, 1450, 1451, 1482
Sterilization devices 1448, 1452
Systems equivalent to Sanitary Canal 1443

Depreciation. See "Cost."

Dilution:
Amount necessary for 6,000,000 population 1489, 1490
Effect of floating population on 1496
Method of treatment by 1421, 1423, 1427
Necessity of conserving dilution water 1508

Disease, Theories of in 1889 1419
Disinfecting Plant (Project A) 1435
Diversion, amount of present 1480, 1481

Estimates (See "Costs.")
Basis of 1454, 1455, 1508
Comparison 1906 and 1913 1458–1462
Effect of water reduction on 1509, 1510

Exhibits:
Defendants:
Fuller's No. 1 1413
Fuller's No. 1 cross examination introduced 1473

Filtration:
Function of 1471, 1489
Intermittent sand, general description 1425, 1456
Percentage organic matter removed by 1502

Fuller, George W.:
Address, Business 1409
Connection with I. W. W. Commission 1462
Description of Chicago Situation (1889–1900) 1413, 1414
Education 1409
Experience 1410
Expert 1411, 1473

  Cost 1449

Land irrigation 1421–1424
Lawrence Avenue Project (Project B) 1433
Maintenance. (See "Cost.")
Metering Chicago water, cost of 1511
North Shore Project 1435
Odors, prevention of 1440, 1441
Operation. (See "Cost.")

Organic Matter Removed, Percent of:
  Settling tanks, by 1502
  Filters, by 1502

Overhead. (See "Cost.")
Oxidation of sewage, purpose of water is 1491
Oxygen content of lake water 1498, 1499
Oxygen necessary in canal 1499

Pollution:
  Advisability of 1418, 1419
  Effect on lake water 1477, 1480, 1489
  Ships as cause of 1470
  Regulation of, from ships 1513

Population:
  Assumed in estimates 1435, 1436, 1441, 1442, 1452
  Effect of floating 1496, 1497

Pumping station 1434
  Cost of 1447, 1449, 1450

Page

Project A: 1442
Cost 1452
Attendance 1450
Depreciation 1450
Itemized 1450–1452
Operation and maintenance 1452
Operating, total 1500, 1501
Differences, fundamental, from Project B 1435
Disinfecting plant
Methods of Disposal:
Sprinkling filters 1431, 1433, 1434, 1449
Sterilization of flood flow 1431, 1498
Pumping station 1434
Result of Method, Ultimate:
All sewage goes into canal 1498
No sewage into lake 1494

Project B: 1442
Cost 1453–1455
Operation, total 1453
Separate system 1500, 1501
Differences, fundamental, from Project A
Method of Disposal: 1434
Calumet Project 1432, 1433, 1434
Intercepting sewers 1433
Lawrence Avenue Project 1432, 1433, 1434
Sedimentation tanks 1433
Separate system of sewers 1433, 1497, 1498
Thirty-ninth Street Project 1433
West Side Project 1434
Pumping station 1501
Reason for suggestion of 1498
Result, all sewage goes to canal 1504

Projects equivalent to 5833 c. f. s. 1434
Pumping station 1419
Purification, state of art in 1889
Reduction of Flow to 4,167 c. f. s.: 1429–1431, 1495, 1496, 1497
Effects of 1431
Remedial measures

Cross-examination 1525-1533
Baltimore situation, discussed....1521, 1522, 1526
Chicago situation, difficulties in....1523–1526

Dilution Method:
Not aided by screening.... 1530
In Washington, D. C.... 1518

Filters:
Extra load on, by added pollution....1531, 1532
Slow sand, at Washington, D. C.... 1520

Phillips, A. E.:
Age, occupation, education, residence.... 1516
Connection with Washington, D. C., sewage works.... 1524
Connection with Washington, D. C., water supply.... 1525
Experience in sewage work....1517, 1524

Potomac River:
Flow of.... 1527
Population sufficient for....1527, 1528

Page

Providence Situation, discussed....1522-1526
Pumping, cost per W. H. P....1524, 1525

Purification:
Of sewage, purpose in large cities.... 1521
In streams, a function of time....1532, 1533

Screening, effect on dilution required.... 1530

Sewage Disposal:
Method of, in large cities of U. S. A.... 1521
System, Washington, D. C.... 1518

Sewage Treatment:
Artificial, methods of future....1522, 1529, 1530
Artificial, not successful.... 1522
Does not reduce dilution required....1519, 1530
Usual purpose of purification in large cities of U. S. A.... 1521
In Washington, D. C.... 1518

Storm water, not pumped in Washington, D. C.... 1519

Washington, D. C.:
Death rate in.... 1524
Dilution method in.... 1518
Phillips, A. E.:
Connection sewage works of.... 1524
Connection water supply of.... 1525
Sewage disposal system, organization of.... 1518
Sewage treatment in.... 1518
Sewage works of, cost of....1520, 1526
Sewage works of, designed by....1519, 1520
Slow sand filtration at.... 1520
Storm water not pumped in.... 1519
Water supply of, Potomac.... 1520
Water works of, cost of.... 1525

E. W. Schoder's Testimony for Defendant.

Direct examination....1533-1550
Cross-examination....1550-1560
Re-direct examination....1561-1563

Cornell:
Laboratory, description of....1534, 1561
Tests, Government, at.... 1562
Weirs, accuracy of measuring at.... 1550

Current Meter: Page
Deficiencies of, from weir ... 1549
No law of variation apparent ... 1550, 1557
Haskell:
Description of experiments made with ... 1534, 1535
Size of, used in measuring large streams ... 1553
Tests on:
By E. W. Schoder & K. B. Turner ... 1535
Discussion of results ... 1555
Purpose of ... 1556

Discharge measurements, personal equation in ... 1563

Error:
In measuring large streams ... 1551, 1553-1555
Relative, in large and small streams ... 1555

Exhibits, Schoder's:
No. 1. Introduced (Photograph of Haskell Current Meter) ... 1535
No. 2-12, incl. Introduced (Photographs of canal, etc.) ... 1536
No. 13. Description of (Table of discharge measurements) ... 1548, 1549

Schoder, E. W.:
Address, occupation, title ... 1533
Experience measuring large streams ... 1550, 1551, 1555
School, experience ... 1534
Tests by, assisted by K. B. Turner ... 1535

Weirs:
Accuracy of measuring at Cornell ... 1550
Deficiencies of current meter from ... 1549

K. B. Turner's Testimony for Defendant.

Direct examination ... 1563-1579
Cross-examination ... 1579-1591
Re-direct examination ... 1591-1592

Canal at Cornell:
Description ... 1583
For public use ... 1591, 1592

Cornell:
Experiments at:
Method of computation of ... 1588
Sources of error in ... 1586, 1589, 1590
Size of meter used at ... 1580
Weir at ... 1585

Page

Current Meter:
- Explanation of discrepancy in test 1586
- Rating of 1582
- Size used at Cornell 1580
- Types of, screw and cup 1581, 1582

Exhibit No. 1 Turner's:
- Conclusion from 1575
- Description of 1571

Measurements, under ice, accuracy of 1577
Schoder's work, relative accuracy, with U. S. L. S 1565

St. Mary's River:
- Fall in 1576
- Measurements of 1564, 1566
- Plottings, vertical velocity curve, Turner's Exhibit No. 1 introduced 1567

Turner, K. B.:
- Address, occupation and experience 1563, 1579
- Connection with St. Mary's 1905 measurements 1564
- Experience with temperature and evaporation data 1564

U. S. lake survey work, relative accuracy with Schoder's 1565

Velocity:
- Percentage variation in, in vertical section 1572
- Variations of, with higher velocities 1578

Weir, at Cornell 1585

GEORGE M. WISNER'S TESTIMONY FOR DEFENDANT.

Direct examination 1592-1646
Cross-examination 1646-1694
Re-direct examination 1694-1697
Re-cross examination 1697-1703
Aeration, report of 1911 1684
Bubbly Creek, description 1605
Calumet River, reversing, need for 1621

Calumet Sag Channel:
- Capacity 1604
- Cost for 2,000 c. f. s 1610
- Cost for 4,000 c. f. s 1612
- Description 1604
- Expenditures on 1653
- Now being constructed 1658
- Purpose of 1649
- Villages and towns on 1604

	Page
Canal, Chicago Sanitary District:	
Capacity at Lockport	1662
Description of main channel	1596
Effects of flow through	1615, 1616
Flow in:	
Actual	1660
Measurement of, method	1619
Regulation of, day and night	1649
Table	1618
Navigability of	1600, 1602
Operation, method	1661, 1663
Present conditions in main channel	1617

Extract from report of U. S. Engr. at Chicago, W. H. Bixby, Dec. 22, 1906, on effect of withdrawal of water from Lake Michigan (H. R. Doc. 6, 59th Cong. 1st Sess.) 2397a
Extract from report of Special Board of Engineers on Waterway from Lockport, Ill., to mouth of the Illinois River, Jan. 23, 1911. (H. R. Doc. 1374, 61st Cong. 1st Sess.) 2397d
Ordinances of the City of Chicago entitled "Sanitary Regulations of Harbor" 2397f
Additional extracts introduced in evidence from the reports of the Chief of Engineers in reference to lake levels, referred to by Prof. Gardner S. Williams and other expert witnesses on lake levels.
International Waterways Commission Progress Report, 1912, Sen. Doc. 959, 62nd Cong., 3rd Sess.
Report of American Section 2398
Niagara River 2398
Chicago Drainage Canal 2401
Summary 2401

Page
Printe
Recor

Capacity of Canal ... 24
Diversion not continuous ... 24
Tacit agreement to 10,000 cfs. ... 24
Lowering of Lakes by 10,000 cfs. ... 24
Lake traffic ... 24
Cost of restoring depths ... 24
10,000 cfs. makes practicable waterway of 14 feet to the Mississippi River. 24
Effect at Niagara Falls of secondary importance ... 24

Recommendations:
Precedence of domestic and sanitary uses ... 24
10,000 cfs. diversions ... 24

Dam at outlet of Lake Erie ... 24
Compensation for Chicago diversion possible ... 24

Report of Full Commission on:
Chicago Drainage Canal ... 24
Historical ... 24
Legislation ... 24
Description of Canal ... 24
10,000 cfs. makes 14 ft. low water channel possible ... 24
Expenditures by Chicago ... 24
Tacit agreement to 10,000 cfs. ... 24
10,000 cfs. diversion recommended ... 24
Effects of diversion ... 24
Variations of Lake Surfaces ... 24
Lake traffic ... 24
Cost of restoring depths ... 24
Calumet Diversion ... 24
Purification of sewage ... 24
Summary ... 24
Recommendations ... 24

International Waterways Commission:
Final report on proposed dam at outlet of Lake Erie. Sen. Doc. 118, 63 Cong. 1st Sess ... 24
Message of President ... 24
Report of Commission ... 24
Dam located near Welland ... 24
Could raise water 4 feet ... 24
Model of dam tested at Cornell University ... 24
Effect on Lake Erie ... 24
Effect on Lakes St. Clair and Huron ... 24
Effect on Barge Canal ... 24
Estimated cost of dam ... 24
Effect on Ontario not serious ... 24

Movable headgates for regulating Niagara River 2647

Surface fluctuations of Lakes Michigan and Huron:

June, 1911 2649

July, 1911 2651

August, 1911 2653

September, 1911 2655

Extract from answer of The Sanitary District of Chicago in suit to restrain the construction of the Calumet Sag Channel 2657

Extract from answer of The Sanitary District of Chicago in suit of the United States to restrain the withdrawal more than 4,167 cu. ft. of water per second 2658

VOL. V.

CLASSIFIED TABLE OF CONTENTS.

E. E. Haskell's Testimony for Complainant.

Page

Direct examination 2659-2675
Cross-examination 2675-2754
Re-direct examination 2754-2761
Re-cross examination 2761-2772

Bazin's Weir Experiments Discussed 2687
Catalog, Ritchie-Haskell 2748
Chezy Formula Discussed 2680, 2763
Compensation, opinion concerning 2744

Cornell Hydraulic Laboratory:
- Accuracy of Weir 2668
- Calibration of Weir 2751
- Changes in Weir 2750
- Duties of E. E. Haskell at 2678
- Haskell's Familiarity with 2749

Current Meters:
- Applicability of "Price" 2748
- Degree of accuracy of Haskell:
  - In open channels 2663, 2745
  - On Niagara River 2664
- Diurnal fluctuations of Haskell 2708, 2737
- Effect of oblique currents on Haskell 2664
- Effect of perturbation on Haskell 2663, 2747
- Errors due to thickening of oil 2737, 2757, 2763
- Haskell types 2679
- Importance of accurate rating 2666
- Methods of rating 2666, 2705
- Multiple sets of 2677
- Percentage of stream covered by meter 2739
- Tests of Haskell:
  - Colored water test 2666
  - Compared with cup meter 2667, 2673
  - Compared with Weir 2667, 2702, 2739

Curvature, effect on stream flow 2720
Deforestation, effect of, on supply of Great Lakes 2755, 2763

Detroit River:
- Relation to Niagara River increment 2696
- Relation to St. Clair River increment 2696

Discharge Equations, applicability of 1912 ..... 2723, 2755

Pa

Discharge Measurements:
Comparison of St. Clair and Niagara....2728, 2
Degree of accuracy of "Mean of"....2
Diversion Effects, conclusions based on records....2

Drainage Canal:
Ease of gaging....2
Velocities in....2
Dredging, effect of, on dredging of Great Lakes....2

Evaporation:
From Great Lakes....2735, 2
Relation of, to diversion....2

Exhibits:
No. 1. Feb. 3, 1914. Identified....2
No. 2. Haskell's, Feb. 3, 1914. Identified....2
No. "A" Haskell's, Feb. 25, 1914. Identified....2
Floats....2
Double....2

Fluctuations:
Accuracy of increment derived from....2
Factors affecting ratio of....2

Francis Weir Experiments:
Experiments discussed....2
Formula discussed....2

Fteley and Stearns Weir Experiments:
Range of "C"....2
Weir Experiments discussed....2085, 2

Gage Records, reliability of....2755, 2

Great Lakes:
Applicability of Eastern runoff data to....2671, 2
Effect of deforestation on supply of....2755, 2
Effect of dredging on regimen of....2
Evaporation from....2735, 2
Runoff and precipitation on....2

Groat, B. F., accuracy of work....2668, 2

Gut Dam, effect of, on Lake Ontario....2

Haskell, E. E.:
Duties at Cornell....2

General....2660, 2
Measuring streams....2
Member I. W. C. C....2
With weirs....2

Ice, effect of in Niagara River....2674, 2710, 2

Page

Increment:
Accuracy of, assuming a straight line 2662
Accuracy of, derived from fluctuations 2674
Comparison of St. Clair and Niagara 2730
Definition of 2717
Degree of accuracy of 2715, 2718, 2757, 2765
Niagara River, accuracy of 2662, 2766, 2769
Quintas Niagara 2690, 2691
Relation, Niagara and Detroit Rivers 2696
St. Clair River 2663, 2696, 2732
St. Lawrence River, accuracy of 2726

International Bridge Section:
Correction for obliquity at 2723
Description 2664, 2706
Effect of eddying water 2665
Personal knowledge concerning 2665
Turbulance at 2665, 2706, 2746
Lake Ontario, effect of Gut Dam on 2744

Measurement of large streams:
Degree of accuracy 2662
Practicability of 2663
Meters, Current. See "Current Meters."

Niagara River:
Comparison of discharge with St. Clair River 2728, 2730
Comparison of increment with St. Clair River 2730
Comparison of St. Clair River with 2690
Comparison of St. Mary's River with 2690
Cross section, accuracy of 2662, 2664
Ice, effects in 2674, 2710, 2757
Increment, accuracy of 2662, 2766, 2769
Increment determined by Mr. Quintas 2691
Measurements, accuracy of 2661
Relation to Detroit River increment 2696
Work of Mr. Quintas 2690, 2691
North Channel, time of construction 2724

Open Section:
Description of 2665
Turbulence at 2665
Precipitation, on Great Lakes 2694
Price Meter. See "Current Meters."

Page

Quintas:
Increment for Niagara River 2691
Work on Niagara River 2690
Rainfall, relation to diversion 2743
Rate of travel, of crest compared with discharge 2705
Ritchie, Haskell Catalog 2748
Russel, Thomas, report discussed 2732, 2757, 2762
Runoff:
Applicability of Eastern data to Great Lakes 2672
On Great Lakes 2694
Schoder:
Experience of 2669, 2749, 2753
Work with Turner, accuracy of 2668, 2669
Schoder and Turner:
Accuracy of work of 2668, 2670
Applicability of work of 2670
Experience of 2669
Shenehon, connection with St. Mary's River work 2719
Split Section:
Description of 2665
Effect of curvature on 2666
St. Clair River:
Check between sections 2662
Discharge compared with Niagara River 2690, 2728, 2730
Increment of 2663, 2696, 2732
Increment compared with Niagara River 2730
Measurements, accuracy of 2662, 2714
Relation to Detroit River increment 2696
Sabin's method of measuring 2677
Sections measured on 2662
St. Lawrence River:
Increment, accuracy of 2726
Measurements, accuracy of 2663, 2732
North Channel, time of construction 2724
St. Mary's River:
Compared with Niagara River 2690
Measurements on 2689
Shenehon's work on 2719
Vertical curves 2670
Work on, accuracy of 2671
Stream flow, effect of curvature on 2720
Surface velocity, in streams 2701, 2756
Susquehanna River, measurements of 2669, 2740, 2762
Three Points Section, perturbation at 2746

Page

Turner:
Accuracy of work....2668, 2669
Experience....2669, 2749, 2753, 2764
Velocity at surface, in streams....2701, 2756

Vertical Curves:
Accuracy of....2703
Of St. Mary's River....2670

Weirs:
Basin's experiments on, discussed....2687
Cornell experimental, changes in....2750
Cornell experimental, calibration....2751
Francis' experiments on, discussed....2683
Francis' formula for, discussed....2682
Fteley & Stearns experiments on, discussed....2685, 2686
Haskell's experience with....2704
Measurements, accuracy of....2688, 2700
Range of "C"....2686
Sharp Edge, discussed....2682
Various forms of....2689

CHARLES Y. DIXON'S TESTIMONY FOR COMPLAINANT.

Direct examination....2773-2779
Cross-examination....2779-2782
Re-direct examination....2782-2783
Re-cross examination....2783
Re-direct examination....2783-2784
Re-cross examination....2784-2787
Re-direct examination....2787-2788
Re-cross examination....2789

Compensation:
Computations of....2784, 2785
In Detroit River....2774, 2775, 2777, 2785
In Livingstone Channel....2774, 2785

Detroit River:
Compensation in. See "Compensation."
Deposition of material in....2774, 2775, 2776, 2777
Depth, original....2782

Effect of excavation in:
On levels of Lake St. Clair....2783, 2784
On navigation....2776
On slope of Detroit and St. Clair rivers....2784, 2785
Government improvements in....2773, 2774
Ice effects in....2778

,Page

Dredging:
At Ballard's Reef 2788
Date of 2775
Material 2775
Dams built for construction purposes 2777
Deposition of material:
Decision of engineer officer regarding 2779-2780
In Detroit River 2774, 2775, 2776, 2777
Effect of, on Lake St. Clair 2777
Effect of 2774
Along Livingstone Channel 2781
Effect of, on navigation 2776
In Detroit River 2774
In Livingstone Channel 2776

Dixon, Charles Y.:
Experience 2773
Present occupation 2773
Training 2773

Ice, effects in Detroit River 2776

Lime Kiln Crossing Channel:
Depth 2774, 2776
Improvements in, date of 2773, 2788
Length 2774
Material excavated from 2774
Width 2773, 2774

Livingstone Channel:
Area of cross section 2785, 2786
Cofferdams in 2777, 2781
Effect of, on Lakes St. Clair and Huron 2787
Effect of removal of 2787
Compensation in 2785
Controversy, U. S. Govt. vs. Contractor 2781, 2782
Depth of 2782
Dredging in 2776
Date of 2776
Material removed, amount 2786
Slope of 2787

Spoil:
Location of 2781, 2782
Removal of 2781-2783
Effect of 2787
Width 2776

Page

Soundings:
Abrupt changes in depth, discussed 2781
Distance between 2781
Dixon's work in 2778
Precision of 2778, 2779, 2780, 2781

F. G. Ray's Testimony for Complainant.

Direct examination 2788-2815
Cross-examination 2816-2841
Re-direct examination 2842-2849
Re-cross examination 2849-2857
Re-direct examination 2857-2858
Re-cross examination 2858-2863
Re-direct examination 2863-2864
Re-cross examination 2864-2865
Re-direct examination 2865

Black River, dredging on 2842
Boats on Great Lakes, size of 2809

Chief of Engineers Reports:
Formulae in 2817
Ray's work on 2816
Diversion at Chicago, effect of 2810, 2811, 2801, 2831
Drift in Lake St. Clair 2829, 2842
Dry Dock Section, conditions of flow at 2791, 2856, 2857

Dredging:
Between Gorge and Dry Dock 2819
Black River 2842
Compensation for (natural on St. Clair) 2842
Effect of, on Lake Huron 2819
Effect of, on St. Clair River 2842

Errors in:
Area of Section 2801
Channels and rivers, comparison 2832
Discharge measurements 2791
Increment of:
Niagara River 2795
St. Clair River 2793
St. Lawrence River 2795
Large and small rivers, comparison 2833, 2846
Soundings 2801, 2837

Page

Exhibits:
Ray's Nos. 1, 2, 3 and 4, Feb. 4, 1914.....2807, 2808
Williams'. See "Williams."

Gage Heights:
Comparison of, for different periods.....2805, 2837, 2839
Velocity and.....2832, 2834
Weighting, Niagara.....2841
Gages on St. Lawrence, instability of.....2792
Gaging large and small rivers, accuracy of.....2833, 2846
Gorge Section, conditions of flow at.....2791
Government Improvements, effect of, on Lakes Michigan-Huron.....2804
Gut Dam, effect of, on discharge measurements.....2793

Ice:
Cover, effect of.....2857
Effect of, on Michigan, Huron and Erie.....2799, 2860, 2861, 2862, 2863
Effect of, on flow of St. Clair.....2845, 2846, 2853
Effect of, on increment.....2800, 2853, 2854, 2858
Gage Heights and.....2852
Jams, simultaneous.....2852
Observations of, conditions.....2830
Sabin's reports on.....2830
Shenehon's reports on.....2830

Increment:
Comparison of, with Haskell's Exhibit.....2809
Changes in.....2848, 2849
Discharge and.....2825, 2826, 2827, 2828, 2852, 2853
Effect on, using data in "Preservation of Niagara Falls".....2808
Elevations and.....2827
Ice effect on.....2800, 2858
Method of determining.....2800, 2839, 2840, 2841
Niagara River.....2794, 2795
St. Clair River.....2793
St. Lawrence River.....2795

Lag. See "Wave Propagation."

Lake Survey:
Accuracy of work of.....2790
Consistency of work.....2801
Ice conditions, observations of.....2830
Men employed by.....2796

Lemont Measurements:
Discharge and stage for.....2834
Peak flow for.....2834, 2847, 2856
Section measured, nature of.....2832

Page

Local Supply:
Determination of, accuracy of 2800
Effect of, on Lake Levels 2837, 2864
Estimating 2800
Magnitude of, for different periods 2837, 2838

Meters:
Used by Lake Survey 2833, 2835
Pitot Tube, check with 2812
Navigation, relation of depth to 2820

Niagara River:
Accuracy of work on 2791
Favorable conditions on 2795
Increment of 2794, 2806, 2809
Surveys of, recent 2829
Pitot Tube, used at Niagara Falls developments 2812, 2813

Rainfall:
Erie Basin 2865
Reliability of old, data 2847

Russell:
Occupation 2850
Reports of, on ice 2851, 2858
Sabin and, comparison of reports 2851

Ray, F. G.:
Connection with Lake Survey Work 2789, 2831
Experience 2788, 2790, 2831, 2836
Former testimony 2788
Occupation 2816

Sabin:
Ice conditions, reports by 2830, 2845
Observations of, number of 2859, 2860
Russell and, comparison of reports 2851

Shenehon, F. C., report on ice 2830
Soundings, accuracy of 2836
Split Section, purpose of recent measurements 2848

St. Clair River:
Bed of, fluctuations in 2822, 2829
Critical section of 2829
Difficulty of measuring 2794
Discharge and elevation of, relation between 2819, 2820
Error in work on 2791, 2793, 2794
Increment of 2793, 2794
Measurements on, number of 2800
Sections gaged 2791

Page

St. Lawrence River:
- Area of section, redetermination of ... 2792
- Error in work on ... 2792
- Increment of ... 2795, 2796, 2849
- Instability of gages ... 2792
- Vertical Curves, redetermination of ... 2793

Sweeping, purpose of ... 2837

Williams' Testimony, Ray's Discussion of:
- Increment, method of computing ... 2802, 2803, 2804
- Increment, by Lake to Lake ratio ... 2799, 2800, 2802-2804
- Observations, weighting ... 2797, 2798, 2803
- Observations, reduction of ... 2796, 2799
- Stage, long time periods ... 2797

Wave Propagation (or Lag):
- Buffalo Gage to section ... 2290
- Drainage Canal ... 2815, 2832, 2847, 2855
- Example of ... 2857
- Formula for ... 2847
- Ogdensburg to Three Points ... 2804
- Velocities and ... 2832, 2834

Welland Canal, work under way on ... 2809

Water Power at Niagara Falls:
- Cost of ... 2814, 2831, 2849
- Horse power per cu. ft. per sec ... 2813
- Measurements in diverting canals ... 2811, 2812, 2813

Y Term in 1912, St. Clair River Equation:
- Changes in ... 2828
- Data used in determining ... 2824
- Discharge and ... 2826
- Explanation of term ... 2820, 2843, 2855
- Formula including ... 2820-2824
- Increment, relation to ... 2824-2827
- Variation in, over period of years ... 2844

SHERMAN MOORE'S TESTIMONY FOR COMPLAINANT.

Direct examination ... 2866-2891
Cross-examination ... 2891-2926
Re-direct examination ... 2926-2930
Re-cross examination ... 2930-2933
Re-direct examination ... 2933
Re-cross examination ... 2933

Page

Adjustments, Changes and Recomputations:
Detail regarding....2867, 2912
Effect of, on discharge.... 2867
Purpose of.... 2867
Co-efficient Work, accuracy of different methods.... 2910

Deflections:
Effect of, on measurements.... 2933
Experiments on.... 2927
Index velocity and....2901-2902
International Bridge.... 2903
Relation between velocity and.... 2926
Diversion at Chicago, effect of, on Lake levels.... 2890

Errors in:
Co-efficients, velocity.... 2870
Deflections.... 2928
Gaging large streams.... 2870
General, from example.... 2909
Increment.... 2869
Measurements.... 2868
Soundings....2906, 2928
Sections, cross.... 2870
Velocity, absolute.... 2870
Volume of flow....2868, 2869
Exhibits, Nos. 1, 2, 3, 4 and 5, Feb. 5, 1914, offered in evidence.... 2884

Gagings:
Accuracy of, in large streams.... 2870
Methods of checking.... 2871
Methods at International Bridge.... 2914

Gorge Section:
Bottom conditions at.... 2874
Soundings at.... 2907
Turbulence at.... 2873
Hydraulic Power Co., horse power development per cu. ft.... 2871

Increment:
Effect of changes on....2867, 2915
Magnitude of....2867, 2869
Methods for determination of....2877, 2878

International Bridge:
Bottom conditions at....2871, 2872, 2902
Deflections at.... 2904
Gagings at.... 2914
Number of Measurements at.... 2904
Soundings at....2907, 2902, 2904, 2906
Turbulence at....2873, 2903

Page

Lag:
- Buffalo Gage to Bridge 2874, 291e
- Buffalo Gage to open section 2874
- Comparison of, in rivers and canals 2919
- Determination of 2874, 2918
- Measurements of, Drainage Canal 2880, 2888

Lemont Measurements (Stevens St. Bridge):
- Area cross section for 2883
- Flow conditions of 2879, 2921-2923
- Instructions for making 2918
- Lag measurements of 2880, 2881, 2918, 2921
- Meters used 2883
- Number of observations 2879, 2920
- Peak flow during 2921, 2923
- Time spent upon 2879
- U. S. Engineer Office, Chicago comparison with 2920, 2929, 2930

Meters:
- Cables for, size of 2900, 2903
- Corrections for 2907, 2924
- Checks on 2871
- Deflection of 2901, 2902
- Moore's use of 2886
- Number of, used 2870
- Rating, change of 2913
- Rating of 2870
- Turbulence indicated by 2873
- Use of 2870
- Variations of 2930

Moore, Sherman:
- Education of 2891, 2911
- Experience of 2886, 2891, 2894
- Testimony of, previous 2886

Niagara Falls Power Company Canal:
- Agreement of work on 2871
- Pitot Tube Check 2871
- Measurement of 2871

Niagara River:
- Changes on 2912
- Conditions of bottom of 2902
- Discharge measurements on 2914
- Increment of 2907
- Turbulence in 2873
- Volume of flow of, error in 2909

Page

Pitot Tube, check with meter 2871
Ray's Exhibits, discussion of 2868
Richmond's Testimony, explanation of "inclusive figures" 2926, 2932
Schoder and Turner, discussion on testimony of 2875, 2876, 2928

Soundings:
- Comparison of Shenehon's and Moore's 2928
- Method of taking 2905
- Method of reducing 2908
- See "International Bridge."
- See "Three Point Section."

St. Clair River:
- Changes in computations of 2914
- Increment of 2869
- Measurements of 2868
- Regimen of, changes in 2877
- Volume of flow in, error in 2869

St. Lawrence River:
- Bottom conditions on 2902
- Changes in computations of 2913
- Discharge measurements on, number of 2901
- Increment of 2869
- Turbulence on 2874
- Volume of flow on, error in 2869

St. Mary's River:
- Changes in measurements on 2912
- Conditions of flow in 2920

Three Point Section:
- Deflections at:
  - Sounding wire 2898
  - Meter Cable 2898, 2899
- Depth at 2898, 2899
- Index velocity 2899, 2901, 2902
- Meter cables at 2900
- Meters used at 2898
- Sounding wire used at 2899
- Soundings at 2898, 2902

Turbulence:
- International Bridge section 2873, 2903
- Open section 2873
- Gorge section 2873
- Indication of, by meter 2873

Page

U. S. Engineer Office, Canal Discharges, Chicago:
Comparison of, with Moore 2930
Method of measurements of 2929
Opinion on work of 2931
Williams' Testimony, opinion on 2877

WALDEMAR S. RICHMOND'S TESTIMONY FOR COMPLAINANT.

Direct examination 2934-2952
Cross-examination 2952-2997
Re-direct examination 2998-3002
Re-cross examination 3002
..... 3013-3019

Catamaran, of the Lake Survey 2942, 3019

Co-efficient Work:
Comparison of, at different depths 2967
Relative accuracy of 2978
Time required for, in general 2967
See particular sections.

Deflections:
Discrepancies between meter and sounding 2971, 2972
Method of taking 3016
See particular sections.

Delta Sections:
Depth of 2967
Time interval 2949
Velocity at 2966

Dry Dock Section, velocity at 2966

Exhibits:
No. 1, Feb. 4, 1914, offered in evidence 2940
No. 2, Feb. 4, 1914, offered in evidence 2940
No. 3, Feb. 4, 1914, offered in evidence 2941
No. 4, Feb. 4, 1914, offered in evidence 2941
A, Feb. 18, 1914 2966
B 2966

Errors in:
Area 2942, 2995
Breaking electric circuit 2938
Co-efficients 2943, 2967, 2978, 2997
Comparison of large and small streams 2950
Deflections 2972
Discharge 2943, 2980
Gage readings 2981

Page

Errors in—Continued:
General 2943
Increment 2946, 3001
Length 2942, 2977
Panels 2998
Placing meters 2963, 2989
Rating curve 2978
Reduction of observations 2981
Velocity 2943, 2979
Volume of flow 2943, 2944

Gages:
Errors in reading 2981
Precautions in reading 2935, 2936
Self registrating on St. Clair River 2935
Time element in reading 2936, 2938

Gaging:
Correction of, for direction of current 2998
Methods of 2942, 2963, 2977, 3014
Meters used in 2960
Purpose of 2935, 3013
Precautions taken in:
Gage reading 2935, 2936
Meter work 2936, 2988
Time element 2936, 2938
Velocity measurements 2936, 2947
Surface conditions during 2947, 2998
Station, location of, in 2964
Time required for 3015
See particular sections.

Gut Dam, effect on Lake Ontario 2993

Gorge Section:
Co-efficient work at 2978
Deflection at:
Meter 2971, 2972
Sounding 2968, 2970
Depth at 2967, 2969, 2970
Index velocity 2968, 2970
Percentage velocity 2968, 2970
Soundings 2968
Traverses, number taken at 2970
Velocities at 2971, 2986
Width at 2968, 2977

Increments 2945-2947, 3001

W. D. Hamilton's Testimony for Complainant.

Direct examination 3031-3033

Chicago River:

Cross currents in 3032
Narrow places in 3031
Velocity of 3032
Worst places in 3031

Hamilton, W. D.:

Address 3031
Employer 3031
Experience in navigation 3031

John Simon's Testimony for Complainant.

Direct examination 3033-3034

Chicago River:
Dangerous places in 3034
Velocity of 3033

Simons, John:

Address 3033
Length of service 3033
Occupation 3033

JOHN F. HAYFORD'S TESTIMONY FOR COMPLAINANT.

Direct examination 3079-3106
Cross-examination 3107-3112

Chicago Diversion:
Effect on Lake Erie 3099

Data Studied by Hayford 3087-3092, 3100

Errors in:
Discharge and Increment—See "Niagara River."
Individual Observations 3091

Evaporation:
Experiments on, under way 3083
Methods of Measuring 3084

Exhibits:
Nos. 1, 2, 3, 4, 5, introduced 3086
No. 6 introduced 3086
No. 7 introduced 3087
No. 8 introduced 3087
No. A, cross-examination, introduced 3108
Objected to 3109-3112

Hayford, John F.:
Connection with Northwestern University 3079, 3107
Data studied 3087-3092, 3100
Education 3079

Experience:
Coast and Geodetic Survey 3080-3082
Cornell University 3080
Expert Computer 3081-3083, 3109
Stream Gaging 3107
Use of Current Meters 3107
Methods followed in computations 3091-3093, 3107-3108

Least Square and Three-Point Methods 3102, 3103

Niagara River Discharge Measurements:
Criteria applied to 3107-3108

Niagara River Discharge Measurements—Continued:
Errors in, due to:
Area of cross-section 3093
Backwater effects 3095
Direction of flow 3095
Fluctuations of Lake 3095
Lag effects 3095
Meter rating 3097
Total effects 3095
Turbulence 3095
Velocity ratios 3095
Weeds 3095
Winds 3095

Niagara River Increment:
Errors in, due to:
Area of cross-section 3097
Backwater effects 3098
Direction of flow 3098
Fluctuations of Lake 3098
Lag effects 3098
Meter rating 3097
Total effects 3098
Turbulence 3098
Velocity ratios 3095
Weeds 3098
Winds 3098

Northwestern University:
Nature of school 3107

F. C. Shenehon's Testimony for Complainant.

Direct examination 3112-3349
Cross-examination 3349-3364
Re-cross examination 3364-3384
Re-direct examination 3384-3385
Re-cross examination 3385
Re-direct examination 3385-3386
Re-cross examination 3386

Backwater, Effect on:
Lake Erie 3270
Lake St. Clair 3284
Niagara River Sections 3142
St. Clair River Sections 3142-3157

Board of Engineers on Deep Waterways:
Niagara Discharge Measurements 3162

Chicago Diversion:
Effect of on Lake Levels....3335-3338
Chippawa Gage:
Affected by Niagara Diversion.... 3202
Description of 3235-3236
See "Lag."

Detroit River:
Effects of dredging on.... 3151

Discharge Computations:
Consistency of:
Complainant's 3146-3148
Defendant's 3148-3149

Dredging:
Detroit River 3151
Effect of, on Lake Levels.... 3334
St. Clair Lake and River.... 3150

Erie, Lake:
Area of 3263, 3350
Backwater effect on.... 3370
Difficulty of relating discharge to stage of.... 3155
Evaporation from 3252, 3264
Fluctuations of, at Buffalo....3153-3154
Improvement, Plans for....3328-3329
Local supply of....3249-3252, 3349
Runoff from, basin....3364, 3381

Errors in, of due to:
Bridge Section Measurements....3154, 3292, 3306
Buffalo Gage 3177, 3178
Comparison of large and small streams....3162, 3285, 3289-3291
Direction of flow.... 3155
Discharge 3153, 3258, 3309
Gage Heights 3235-3236
Gut Dam, being neglected.... 3149
Ice Effects 3118, 3152

Increment of:
Niagara River 3141, 3149
St. Clair River....3149, 3159
St. Lawrence River....3149, 3150, 3159, 3184

Open Section Measurements....3292, 3154, 3155
Sanitary Canal Discharge....3153, 3291, 3292
Storage Changes 3150
Winter Measurements, inclusion of 10.... 3118

Evaporation on Great Lakes.....3365, 3366

Evaporation on Lake Erie Basin..... 3252

Exhibits of Francis C. Shenehon:

A. Also "Williams Cross 3":
Plotting Niagara Discharge Measurements:
Introduced (Shenehon) 3113

B. Also "Haskell No. 1, Feb. 3, 1914":

St. Lawrence River 3149

Increment:
Discussion of Three Point, Least Squares and String Methods.. ....3129, 3130
Fluctuations of Lake, effect on.... 3131

Shenehon's Method of Determining:
Including local supply.... 3140
Niagara 3141, 3159
St. Clair 3142, 3159
St. Lawrence 3142, 3159

Shenehon's Preference for Value of Niagara....3141-3159
Stearn's Method of Determining.... 3139
Variation of (shown in Table 25, Williams' Exhibit 34)..... 3132

Williams' Method of Determining:
Backwater Effect 3130, 3132
Grouping Observations 3133
Method of Fluctuations....3133, 3138, 3140, 3149
Niagara River 3135
St. Clair River....3130, 3131, 3133, 3134, 3137, 3149
St. Lawrence River.... 3137
Three Point Method.... 3129
Weighing Observations 3133, 3134

International Bridge Section:
Area of 3296
Clearness of water at.... 3303
Depth of 3298
Determination of direction....3303-3306

Gaging at:
Cables used 3298
Drift 3297, 3298, 3299, 3300
Meters, how maintained on section 3296, 3297, 3324
Stewarts' Measurements 3298-3301
Size of piers....3301-3302
Turbulence 3154, 3303, 3306
Unexplored area at....3293, 3295

Lag (Travel or Wave Propagation):
Buffalo to International Bridge....3168, 3173
Buffalo to Chippawa....3200, 3203, 3204, 3124, 3136
Effect of, etc....3204 to 3207, 3208 to 3221, 3206 to 3245
....3351 to 3356, 3366, 3367, 3370, 3384, 3385
Effect of weeds, winds, elevation and barometric pressure on....3229, 3230
Effect of change of draft of Niagara Power Companies on....3205, 3206, 3207
Buffalo to International Bridge and International Bridge to Chippawa, ratio....3266, 3267
Buffalo to Open Section.... 3168
Buffalo to Split Section....3168, 3175
Buffalo to Suspension Bridge....3136, 3200, 3269-3272
Buffalo to Whirlpool.... 3276
Effect of, on Increment....3170, 3176, 3283, 3357
Laws of....3200, 3201
Measurements of 1907-1908.... 3194
Method of Determining....3168, 3169
Niagara River:
Unimportant.... 3197
Niagara and Lemont, compared.... 3174
Ogdensburg to Three Points.... 3187
Rate of Rise and....3271, 3272
Reservoir Effect, effect on....3173, 3174, 3175, 3195
Tables of, how made....3274, 3275

Lemont Measurements, by Moore....3171, 3174, 3291, 3292, 3295

Local Supply—See "Runoff."

Meters:
Current travel between oilings:
During coefficient work at International Bridge.... 3379
During gagings at International Bridge....3375-3378
During gagings at Open Section....3376-3380
During ratings....3374, 3378
Unimportant.... 3386

Ice on....3309, 3310
Ratings at Buffalo Reservoir.... 3373
Rating with colored water.... 3156
Used at Bridge Section.... 3384
See "Gaging" under International Bridge, Niagara River.

Mississippi River Measurements:
Comparison of with Lake Survey work.... 3340
Description of, by Starling....3341-3342
Table from Commission, Described.... 3340

Navigation, effect on, from diversion at Falls.... 3361
Navigation, near Niagara Falls.... 3360

Niagara Falls Diversion:
Amount of, by Treaty 3345
Effect of, on Chippawa Gage 3207, 3212
Effect of, on Lake Levels 3363, 3368, 3369
Effect of, on Navigation 3360

Niagara River:
Corroboration of different sections 3160
Depth of, average Buffalo to Chippawa 3231, 3265
Discharge of, error in 3153, 3285, 3286
Discharge measurements on, number of 3193
Discharge measurements on, best 3170
Gages on, weighted 3198
Ice effects on 3149
Increment of—See "Increment."
Rapids on, depth of 3200

Open Section:
Floats used to determine direction 3304

Oswego Gage, corrected for Gut Dam 3200, 3358

Perturbation—See "Turbulence."

Plate 10, Williams' Exhibit 34, description of 3150

Rainfall:
Comparative reliability of rainfall and runoff data 3383
On Lake Erie Basin 3252, 3253
Relation of, to runoff 3364

Range:
Lake Huron at Harbor Beach 3178

Runoff:
Data, compared with rainfall 3383
Erie Basin 3364, 3381
Great Lakes Basin, average 3320
Maumee River 3381, 3382
Relation of, to rainfall 3364

Shenehon, Francis C.:
Duties in University of Minnesota 3112
Expert testimony of 3113
Previous testimony in this case 3112, 3164
Private practice of 3113, 3345, 3348, 3361
Subsequent experience of 3112, 3164
Time spent on this case 3113

Soo Power Companies, Restrictions on 3332

Stages of Great Lakes:
Comparison of Mean 3329-3332

Stearns, Frederick P.:
Method of determining increment..... 3139
Method of determining runoff..... 3144
Testimony based on Williams' computations..... 3136

St. Clair Lake:
Backwater effects on..... 3284

St. Clair River:
Backwater effects on..... 3160
Discharge of 3283, 3310
Discharge of, checks on.....3343, 3344
Discharge of, error in..... 3153
Dredging on 3150, 3151
Ice effects on.....3152, 3317

Increment of (Shenehon's)—
See also "Increment".....3159, 3183, 3199, 3254
Increment of, errors in.....3183, 3184
Increment of, Williams'..... 3255

Turbulence:
Bridge Section 3154, 3303, 3306
Freeman's testimony regarding..... 3158
Investigation of, Niagara River..... 3159
Open Section 3154
Split Section 3153
Vertical curves, comparison of, for three rivers to indicate.3155, 3156
Winter Section, Calops Rapids..... 3161

VOL. VI.

CLASSIFIED TABLE OF CONTENTS.

DENNIS MCCARDHY'S TESTIMONY FOR DEFENDANT.

Direct examination 3387, 3398
Cross-examination 3398, 3403
Re-direct examination 3403

Chicago River:
- Collision of boats on 3395, 3401, 3402
- Condition of, as to navigability 3391
- Depth of 3390, 3394, 3399
- Dredging on 3399
- Freshets on 3397, 3398, 3402

Improvements to:
- At Halsted and 22d streets 3394
- At Ogden Slip to 22d street 3394
- Under way 3392, 3396

Scows on, capacity of 3389, 3397, 3398
Ships on, number of 3401
Tonnage on 3402

Velocity of:
- At Congress street 3393
- At Penna. R. R. bridge 3393
- At Washington street 3392

Work of Sanitary District on 3391
Work of U. S. Government on 3391

McCardhy, Dennis:
- Experience 3388-3389
- Familiarity with Chicago River 3387, 3388, 3389
- Residence 3387

GEORGE M. WISNER'S TESTIMONY FOR DEFENDANT.

Direct examination in surrebuttal 3403-3435
Cross-examination 3435-3493
Re-direct examination 3494-3500
Re-cross examination 3500-3505

Chicago, Area of 3472

Chicago Drainage Canal:

Capacity of 3476-3478
Dredging on 3416-3418, 3496
Erosion of banks 3461-3463
Flow in 3491, 3492, 3499, 3500
Sewer outlets into 3469-3471, 3474

Chicago Drainage Canal Tests:

Accuracy of 3436, 3466, 3467
Coefficient work 3411, 3443
Computations and reductions 3415
Factors affecting flow 3441-3443, 3465, 3466, 3492, 3500, 3501
Lake Michigan fluctuation during 3408, 3420, 3438, 3460
Lemont measurements, comments on 3420
Men engaged on 3415, 3436
Meters used on 3414
Sections, choice of 3456, 3457

Test of February 22, 1914—See "Tests," below.
Test of March 8 and 9, 1914—See "Tests," below.

Chicago River:

Bridges on 3482-3487, 3499
Floods of 10,000 c. f. s. 3471-3473
Navigation on—See "Navigation."
Reversal of flow 3432, 3433
Storm Water Tests—See "Storm Water Test."
Velocities in 3489, 3490, 3499
Watershed 3471
Width 3488, 3489

Exhibits of George M. Wisner:

No. 7. Introduced and described 3422, 3423
No. 8. Introduced and described 3422, 3423-3425, 3427
No. 9. Introduced and described 3422, 3425, 3426
No. 10. Introduced and described 3422, 3426
No. 11. Introduced and described 3422, 3426, 3427
No. 12. Introduced and described 3430, 3431
No. 13. Introduced and described 3430, 3431
No. 14A. Introduced and described 3434
No. 14B. Introduced and described 3434
No. 14C. Introduced and described 3434
No. 14D. Introduced and described 3434
No. 14E. Introduced and described 3434, 3450, 3451, 3467
No. 14F. Introduced and described 3434
No. 14G. (Chart 34A) Introduced and described 3463, 3464

Illinois River:

Illinois and Michigan Canal, capacity and effect 3432-3435
Dams lowered by Sanitary District 3435

Navigation on Chicago River:
Critical points for....3426, 3427
Docking of vessels....3438, 3439
Improvements in, by Sanitary District....3424-3429, 3498

Power on Chicago Drainage Canal....3491, 3492
Storm Water Tests....3416-3419, 3473, 3474

Test of February 22, 1914—Chicago Drainage Canal:
Dearborn Street Section....3406-3408
Error in discharge measurements.... 3405
Flow....3405-3407, 3415, 3416
Lemont Section 3406
Measurements, how made....3405, 3406
Power house at Lockport....3405, 3408
Summit Section 3406, 3408, 3420, 3443
Weather conditions 3439, 3443

Tests of March 8 and 9, 1914—Chicago Drainage Canal:
Controlling works and power house:
Capacity of 3475, 3477
Discharge at 3411, 3468, 3503
Discharge at different sections compared....
....3447-3454, 3458-3461, 3465, 3469, 3494-3496
Measurements at, how made.... 3457
Accuracy of 3457, 3504, 3505
Compared with Lemont, gagings.... 3469
Sections compared 3447-3449, 3496

Dearborn Street Section:
Accuracy of gagings....3437, 3438, 3439
Conditions at 3459, 3460, 3490
Discharge at 3414, 3490
Interruptions to measurements at....3412, 3414
Location of 3411, 3438
Flow previously adjusted....3409, 3410

Lemont Section:
Accuracy of gagings....3444, 3445, 3454
Effect of sewage.... 3465
Coefficient work at.... 3444
Compared with Moore's....3454, 3455
Conditions at 3455
Discharge at 3412
Gage at, time of changes in....3419, 3420
Interruptions to measurements at.... 3413
Location of 3444
Meter used 3466

Lockport Section:
Accuracy of gagings....3444, 3445, 3446
Conditions at....3455, 3456, 3458
Discharge at....3411
Location of....3456
Meter used....3466

Loomis Street Section:
Accuracy of gagings....3438, 3439
Conditions at....3459
Discharge at....3413
Location of....3411

Power House—See "Controlling Works," above.
Reasons for making....3439, 3440, 3443

Robey Street Section:
Accuracy of gagings....3458
Conditions at....3458
Discharge at....3413
Gage at, time of changes in....3420
Location of....3410

Storage:
How determined....3448, 3464
Accuracy of....3462, 3463, 3496
Weather conditions....3443

Willow Springs Section:
Accuracy of gagings....3444, 3445, 3446
Conditions at....3455, 3458
Discharge at....3412
Gage at, time of changes in....3420
Location of....3411, 3455
Meter used....3466

GARDNER S. WILLIAMS' TESTIMONY FOR DEFENDANT.

Direct examination in surrebuttal....3505-3538
Cross-examination....3538-3589

Chicago Drainage Canal, Flow Affected by:
Floating ice....3553-3558
Lake levels....3554
Temperature of water....3553-3555, 3558

Chicago Drainage Canal Tests:
Applicability of, to outlets of Great Lakes....3536-3537
Date of....3534, 3535
Extent of....3531, 3534
Personnel of party on....3532, 3534
Results of....3535-3537

Cornell, Accuracy of Weirs at.....3509, 3546
Direction Meter, Description of..... 3546

Drift of Meter:
Amount computed 3528
Analysis of, by C. B. Stewart.....3522, 3561
Effect of, on Niagara measurements.....3520, 3521, 3529, 3530
Methods used to decrease.....3521, 3525, 3561
Method of determining.....3560-3562

Exhibits of G. S. Williams:
36. Direction Measurements of Vertical Curves International Bridge:
Introduced and described.....3510, 3511, 3512
37. Lake Levels, Niagara River Vertical Curves, International Bridge:
Introduced and described.....3516-3518
38. Niagara River Section Oakfield Vertical 8:
Introduced and described.....3518, 3519
39A. Hourly Elevations:
39B. Buffalo and Chippawa:
Introduced 3519, 3520
40. Plate from C. B. Stewart's Paper:
Introduced and described.....3522, 3524-3526, 3560

Gages:
Accuracy of U. S. L. S. in general.....3544, 3545

Haskells' Exhibit "A" explained.....3512, 3513

Ice Effects:
Accuracy of Russell's conclusions..... 3507
Accuracy of Sabin's conclusions.....3506, 3538
Classifications of 3507
On Chicago Drainage Canal.....3538-3541, 3553, 3558, 3503
On St. Clair River..... 3503

Index Velocity:
Error from using.....3519, 3559
How determined 3513
Relation of, to increment.....3513-3515, 3559
Tests on, at Cornell.....3559, 3560

International Bridge Section:
Magnetic observations at.....3545, 3546
Pier at, size and shape.....3530, 3564
Velocity below piers..... 3563

Lake Erie:
Change of elevations in February, 1901....3539-3545
Normal rise during February.... 3505

Letters and Permits, Various....3569-3588
Methods of Computation, Complainant's and Defendant's.... 3537
Navigation in Chicago River, Ice Conditions....3556-3558
Niagara River, Effect of Fluidity on Discharge....3546, 3555
Schoder's Experiments, Accuracy and Applicability....3509, 3510
Stewart, C. B., Experience of....3522, 3523

Tests of University of Michigan:
Applicability of Niagara measurements.... 3531
By whom made....3526, 3527, 3552
Extent of 3527-3528
Meter and weight used....3550-3552
Methods 3547, 3548, 3559
Plant, description of....3546, 3547, 3549, 3552
Purpose of 3526
Results of 3528, 3547

ISHAM RANDOLPH'S TESTIMONY FOR DEFENDANT.

Direct examination 3589-3600

Chicago Drainage Canal:
Inspection of, by Government officials....3592, 3593
Power possibilities 3599

Chicago River:
Flow in 3594
Improvement of, project of 1900.... 3593

Des Plaines River:
Power from Chicago diversion....3598-3599

Illinois River:
Power from Chicago diversion....3598-3599

Navigation on Chicago River:
Condition of, prior to and after Sanitary District improvements. 3595

Navigation on Great Lakes:
Capacity of vessels, total, 1913.... 3600
Freight carried, 1913.... 3600
Retardation to, in shoal water....3596-3598

Randolph, Isham:
Qualifications 3589-3591, 3593

EXTRACTS FROM PROCEEDINGS BEFORE THE SECRETARY OF WAR IN CONNECTION WITH APPLICATION OF THE SANITARY DISTRICT FOR PERMISSION TO DIVERT 10,000 CUBIC FEET OF WATER.

Page

Appearances:
- Hearing February 28, 1912....3001-3002
- Hearing March 27, 1912....3629-3630

Application of Sanitary District of Chicago, February 5, 1912...3602-3603

Briefs and Memoranda:
- Canada, Government of, Brief....3631-3654
- Canada, Government of, Reply Brief....3711-3732
- Canada, Commission of Conservation, Memorandum....3654-3661
- Chicago, City of, Brief by L. E. Cooley....3325-3345
- Cleveland, Brief of Chamber of Commerce....3626-3628
- Dominion Marine Association of Canada, Memorandum....3661-3666
- Illinois, State of, Brief by Isham Randolph....3775-3822
- Lake Carriers Association, Memorandum....3619-3623
- Montreal, Board of Trade, Memorandum....3670-3672
- Montreal, Harbor Commissioners, Memorandum....3669-3670
- Richelieu and Ontario Navigation Company, Memorandum..3680-3681
- Sanitary District of Chicago, Reply Brief....3682-3710
- Shipping Federation of Canada, Memorandum....3676-3678
- Zinn, Colonel George A., Memorandum....3732-3735

Expenditures for Harbors and Channels to 1911....3624-3625

Letters, Resolutions and Statements of Approval:
- Bartow, Edw., to Sec. of War....3823-3824
- Chicago Association of Commerce Resolutions....3774-3775
- Cook, P. T., to Secretary of War....3771-3772
- Cullom, S. M., U. S. Sen. to Sec. of War, Letter.... 3774
- Deneen, Gov. C. S., to Sec. of War, Letter.... 3775
- Farwell, J. V., to Pres. Taft.... 3832
- Federation of South End Civics Bodies, to Sec. of War:
  - Letter....3824-3826
  - Resolutions....3826-3828
  - Letter....3829-3831
- Forgan, D. R., to Pres. Taft, Letter....3831-3832
- Illinois River and Lake Com. to Sec. of War, Letter.... 3773
- Lee, H. W., C. E. to Sec. of War, Letter....3824-3826
- Letter....3829-3831
- McCann, Lawrence, Statement to Sec. of War....3834-3835
- McCormick, Robert R., to Sec. of War, Letter.... 3773
- McVeigh, Franklin, to Sec. of War, Letter....3832-3834
- Noble, Alfred, C. E. to San. Dist., Letter....3828-3829
- Rees, Thos. H., U. S. Eng., to Chf. of Eng, Letter....3767-3770

Page

Secretary of War, Extracts from Proceedings before—Continued:
Rees, Thos. H., U. S. Eng, to Chf. of Eng., Letter.....3770-3771
River and Lake Commission, to Sec. of War, Letter..... 3773

South End Civic Bodies, Federation to Sec. of War:
Letter 3824-3826
Resolutions 3826-3828
Letter 3829-3831

State Water Survey to Sec. of War, Letter.....3823-3824
Wright, C. W., to Pres. Taft, Letter..... 3823

Letters, telegrams, resolutions of protest from various states, cities, chambers of commerce, associations, and individuals:
Association of Drainage and Levee Districts of Illinois, Resolutions 3755-3757
Beardstown, Illinois, Chamber of Commerce, Resolution....3760-3761
Beardstown, Illinois, City of, Resolution..... 3759
Buffalo, New York, Chamber of Commerce.....3749-3750
Buffalo, New York, Shipmasters' Association 3751
Canadian Niagara Power Company, Protest..... 3753
Charlevoix, Michigan, Telegram from Mayor and Chamber of Commerce 3745
Chillicothe, Illinois, Protest.....3757-3758

Signer, Fred E., Association of Lake Lines....3616-3617
Smith, Senator William Alden, of Michigan.... 3604
Spence, F. S., Toronto Harbor Commission....3667-3669
Sullivan, Arthur, Shipping Interests of Chicago.... 3616

VOL. VII.

CLASSIFIED TABLE OF CONTENTS—EXHIBITS.

Exhibits Attached to Bill of Complaint of the United States, No. 114.

Number	Name	Page
A	War Department Permit, May 8, 1899. Permits 200,000 cubic feet per minute	1
B	War Department Order, April 9, 1901. Orders observance of 1899 permit	2
C	War Department Letter, July 23, 1901. Grants 300,000 cubic feet per minute between hours of 4 p. m. and midnight	3
D	War Department Permit, December 5, 1901. Permits not to exceed 250,000 cubic feet per minute throughout 24 hours	4
E	War Department Permit, January 7, 1903. Permits 350,000 cubic feet per minute till March 31, 1903	5
F	Sanitary District Letter, February 5, 1912. Application for 10,000 C. F. S.	6
G	War Department Letter. Reply to application for 10,000 C. F. S.	7

Exhibits Attached to the Answer of the Sanitary District of Chicago.

A	Copy of Act of May 29, 1899, creating the Sanitary District, and amendments thereto	19
B	Outline map of Chicago River and branches	21
C	War Department Letter, March 14, 1907. Relates to reversal of flow of Calumet River	23
D	War Department Letter, September 11, 1907. Permit to construct north shore channel	26
E	War Department Letter, June 30, 1910. Permit to construct Calumet Sag channel	27
F	Memorial to Congress on the subject of the Illinois and Michigan Canal, Laws, Extra Session, 1826, p. 97	29
G	Ordinance (June 5, 1865) for cleansing Chicago River	31

Exhibits Attached to the Answer of Sanitary District—Continued:

Number	Name	Page
H	Sanitary District Letter, June 16, 1896. Application for improvement of Chicago River; also map of Chicago River accompanying same	32
I	War Department Letter, July 3, 1896. Permit for the improvement of Chicago River	37
J	Sanitary District Letter, April 26, 1900. Application for improvement of Chicago River	38
J1	Sanitary District Letter, June 7, 1900. Relative to improvement of Chicago River	39
K1 and K2	Maps of Chicago River, 18th to 31st streets. Sent to Secretary of War, June 7, 1900	41
L	War Department Letter, June 11, 1900. Permit to improve Chicago River	43
L1	War Department Letter, July 11, 1900. Permit to improve Chicago River	44
M	Map of Sanitary District of Chicago, 1913	47

COMPLAINANT'S EXHIBITS.

Number	Name	Page
1	Discharge Curve—St. Clair River Increment—23,820 C. F. S.	49
2	Discharge Curve—St. Lawrence River Increment—28,870 C. F. S.	51
3	Discharge Curve—Niagara River International Bridge Section Increment—21,900 C. F. S.	53
4	Discharge Curve—Niagara River Open Section Increment—21,640 C. F. S.	55
5	Hydrograph (1860-1912, inclusive). Monthly water levels Lakes Superior, Michigan, Huron, Erie, Ontario	57

DEFENDANT'S EXHIBITS.

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

9	Chart of Detroit River	75
10	Chart, Lower Detroit River, showing Livingstone Channel	77
11	Chart, Lake Erie, including the waterways between Lakes Ontario and Huron	79
12	Chart, Buffalo Harbor and Niagara River to the Falls, New York	81
13	Chart, Niagara River from above the Falls to Lake Ontario	83
14	Chart, Lake Ontario	85
15	Chart No. 6, St. Lawrence River	87
16	Chart No. 5, St. Lawrence River	89
17	Chart No. 4, St. Lawrence River	91
18	Chart No. 3, St. Lawrence River	93
19	Chart No. 2, St. Lawrence River	95
20	Chart No. 1, St. Lawrence River	97
21	Seven (7) sheets, containing the U. S. Lake Survey Discharge Measurements of the St. Clair River, Dry Dock Section, 1899, 1900, 1901, 1902, 1903	99-105
22	Six (6) sheets, containing U. S. Lake Survey Records of St. Clair River, as follows	106-111
	Sheet 1. Mean Slope, November-December, 1903	106
	Sheet 2. Summary of 1903 Gorge Section Discharge Measurements	107
	Sheet 3. Summary of 1903 Dry Dock Section Discharge Measurements	108
	Sheet 4. Discharge Measurements, Gorge Section, 1903, 1909	109
	Sheet 5. Same as Sheet 4, 1909	110
	Sheet 6. Discharge Measurements, Dry Dock Section, 1903	111

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

Number	Name	Page
23	Thirty-seven (37) sheets containing U. S. Lake Survey Records of St. Clair River, as follows	112-148
	Sheets 1-9, incl., Daily Mean Water Surface Elevations	112-120
	Sheet 10. Observation on Time of Travel of Wave.	121
	Sheets 11-14. Discharge Measurements George Section, 1910	122-125
	Sheet 15. Discharge Measurements Dry Dock Section, 1910	126
	Sheets 16-22. Summary Discharge Measurements. Delta Section	127-133
	Sheets 23-25. Sketches showing location of Sections and Gages on St. Clair River	132-136
	Sheet 26. Curves of Local Slope Head of River	137
	Sheet 27. Discharge Curve St. Clair River. Increment = 35,145	138
	Sheets 28-31. Current Velocity curves showing effect of passing vessels	139-142
	Sheets 32-37. Cross Sections. Delta Sections	143-148
24	Five (5) sheets containing summary of discharges of Niagara River, 1898, 1899, 1900	149-153
25	Two (2) sheets containing summary of discharges of St. Lawrence River, 1900, 1901	154-155
26	Six (6) tables giving Monthly Mean Elevations of Water Surface of Lakes Superior, Michigan, Huron, St. Clair, Erie and Ontario, 1860-1913 inclusive	156-167
27	Three (3) tables giving Monthly Mean Elevations of Water Surface, as follows	168-170
	Table 1. Detroit River at Amherstburg, Ont.	
	Table 2. Lake St. Clair at Windmill Point.	
	Table 3. Detroit River at Fort Wayne.	
28	Eight (8) sheets of Daily Mean Elevations of Water Surface, Lakes St. Clair and Huron, during periods of discharge measurements	171-180
29	Nineteen (19) sheets of Daily Mean Elevations of Water Surface as follows	181-200
	Sheets 1-7 incl.., Amherstburg, Ont., 1898, 1899, 1900, 1909, 1910.	
	Sheets 8-14 incl., Cleveland, Ohio, 1898, 1899, 1900, 1909, 1910.	
	Sheets 15-29 incl., Buffalo, N. Y., 1898, 1899, 1900, 1901, 1902, 1909, 1910.	

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

Number	Name	Page
30	Five (5) sheets of Daily and Monthly Mean Elevations of Water Surface, as follows	201-205
	Sheet 1. Miscellaneous Automatic Gage Records.	
	Sheets 2-3 incl. Daily, Oswego Records, 1900, 1901.	
	Sheets 4-5 incl. Daily, Ogdensburg Records, 1900, 1901.	
31	Seven (7) tables giving the mean monthly and annual rainfall on Lakes Superior, Michigan, Huron, Erie and Ontario, 1895-1906	206-210
32	Pages 2855-2883, Appendix FFF 2, Annual Report Chief of Engineers for 1903, being the Report of E. S. Wheeler upon Outflow, Rainfall and Evaporation in the Valley of Great Lakes	211-247
33	Report of the International Waterways Commission on Regulation of Lake Erie, 1910	248-347
34	Consisting of a series of 65 Tables, 6 Charts and 11 Plates based on Williams Exhibits 1 to 33 incl., and 35 in this case, and the Records of United States Lake Survey, Reports of the Chief of Engineers, U. S. A., of the United States Geological Survey and of the United States Weather Bureau; and of Officials of certain States and Municipalities. (For Index See VII, 350-355)	349-547
35	Five (5) Charts of Plottings of Daily Mean Elevation of Water Surface, as follows	548-567
	Chart I. Lakes Huron and St. Clair, 1899, 1900, 1901	548-550
	Chart II. Lakes Huron and St. Clair, 1908, 1909, 1910	550-555
	Chart III. Lake Erie at Cleveland, 1898, 1899, 1900	556-560
	Chart IV. Lake Erie at Buffalo, 1898, 1899, 1900	561-565
	Chart V. Lake Ontario, Ogdensburg and Oswego, 1900, 1901	566-567

FREDERICK P. STEARNS' EXHIBITS FOR DEFENDANT.

1	Seven (7) tables as follows	568-574
	Table A, Local Supply and Storage, Lake Ontario	568
	Table B, Local Supply and Storage, Lakes St. Clair and Erie	569
	Tables C and D, Niagara River Discharge Deduced from St. Lawrence River Discharge	570, 571

FREDERICK P. STEARNS' EXHIBITS FOR DEFENDANT.

Number	Name	Page
	Tables E and F, St. Clair River deduced from Niagara River	572, 573
	Table G, Comparisons of Discharges St. Lawrence and St. Clair Rivers	574
2	Four (4) charts, being plottings of following	575-581
	Chart 1. Stearns Exhibit 1, Table C	575
	Chart 2. Stearns Exhibit 2	577
	Chart 3. Stearns Exhibit 1, Table F	579
	Chart 4. Stearns Exhibit 1, Table E	581
3	Table giving Niagara Discharge deduced from St. Lawrence 1912 Discharge Curve	583

JOHN R. FREEMAN'S EXHIBITS FOR D.

1	Studies Relative to Chicago Drainage Cana.	60
2	Reproduction of Record of U. S. L. S. Gauge [illegible] ay 17, 1899, at Head of St. Clair River	587
3	Hydrographs of Lakes Huron, St. Clair and Erie and Fall of Detroit and St. Clair Rivers, 1873-1898	588
4	Article of B. F. Groat on Current Meters, Paper No. 1259, Transactions Am. Soc. C. E.	589-654
5	Plotting Illustrating Time Interval between gages on St. Clair River	655
6	Plotting showing change in current velocity following fluctuations in water level	656
7, 8 and 9	Plotting showing pulsations of current at Section Dry Dock	657-659

HENRY C. ADAMS' EXHIBITS FOR DEFENDANT.

1	Chicago Death Rates—All causes, 1887-1912	661
2	Plotting of Chicago Death Rates, 1860-1912	663
3	Table comprising death rates—Impure air diseases and impure water diseases, 1887-1912	663
4	Distribution of deaths from Typhoid by sex and age	664
5	Decrease in death rates since opening of Drainage Canal	665
6	Map of Manufacturing Zone of Chicago	666
7 & 8	Federal Forms for reporting boat record	667
9	Plotting of prices of pig iron and rails in Pennsylvania 1895-1911	669
10	Comparison average monthly prices heavy steel rails in England and United States, 1895-1911	671
11	Plotting average prices light and heavy steel, 1895-1911	673
12	Plotting average prices iron and steel, 1895-1911	675
13	Summary Table of loss that would be sustained by Chicago were present facilities for pure water impaired or destroyed	677

POOR COPY

GEORGE W. FULLER'S EXHIBITS FOR DEFENDANT.

Number	Name	Page
1	Map of Sanitary District Boundary and the corporate limits of Chicago	679

KENNETH B. TURNER'S EXHIBITS FOR DEFENDANT.

1	Vertical Velocity Curves, St. Mary's River	681

ERNEST W. SCHODER'S EXHIBITS FOR DEFENDANT.

1	Photograph of Haskell Current Meter	683
2-12 (incl.)	Photograph of Cornell University Canal	684-694
13	Table of Discharge Measurements by Haskell Current Meter in Cornell University Hydraulic Laboratory	695

ADDED

GEORGE M. WISNER'S EXHIBITS FOR DEFENDANT.

1	Map showing the limits of the Sanitary District of Chicago	697
2	Map showing parts of Cook, Will and DuPage Counties and the Sanitary District	699
3	Chart showing saving to community by reduction of Typhoid Fever since opening of Drainage Canal	701
4	Plotting of Typhoid Fever Death Rates at Chicago, East Chicago, Hammond and Whiting	703
	Hydrograph average monthly elevation water surface Lake Michigan, 1889-1899 and 1900-1910	705

COMPLAINANT'S EXHIBITS IN REBUTTAL.

WALDEMAR S. RICHMOND'S EXHIBITS FOR COMPLAINANT.

1	Report of W. S. Richmond on Discharge of Niagara River at Split Section	707-709
2	Still Water Rating Curves of U. S. Lake Survey Current Meters	711
3	Niagara Discharge Plotted against Buffalo Gage	713
4	Cross Sections Wickwire and Oakfield and Transverse Velocity Curves	715

SHERMAN MOORE'S EXHIBITS FOR COMPLAINANT.

4 (incl.)	Discharge Measurements Chicago Drainage Canal, Lemont, Illinois, Feb. 5, 1914	717-720
5	Mean 24 hour Curve of Flow, Chicago Drainage Canal, Lemont, Ill.	721

FRANCIS C. SHENEHON'S EXHIBITS FOR COMPLAINANT.

A	Plotting of Discharge Measurements and lines for increments 24,000 and 21,600 C. F. S.	723

FRANCIS C. SHENEHON'S EXHIBITS FOR COMPLAINANT.

Number	Name	Page
B	Plotting of Increment of Niagara—21,900 C. F. S. (Bridge Section), and lines showing departure of one, two and three per cent	725
C	Plotting of 30 Measurements of Niagara River (Bridge Section), used by G. S. Williams, also winter measurements included by mistake	727
D	Same as B, only using Open Section Measurements and Increment = 21,640 C. F. S.	729
D-1	Plotting of 89 Measurements of Niagara River (Open Section, used by G. S. Williams	731
E	Plotting Equations of Discharge Suspension Bridge and Whirlpool	733
F	Plotting of Discharge Curve of Niagara River Suspension Bridge Gage	735
G	Plotting of Discharge Curve of Niagara River Whirlpool Gage	737
H	Plotting of Relative Fluctuations of Whirlpool and Gorge Pool Gages	739
I	Plotting of Relative Fluctuations of Water Surfaces, Lakes Huron and St. Clair	741
J	Plotting of Relative Fluctuations of Water Surfaces, Lakes Erie and Ontario before and after Gut Dam	743
K	Three Curve Series—Sheet 1—Water Level and Discharge Curves, Lake Erie and Niagara River	745
L	Three Curve Series—Sheet 2	747
M	Three Curve Series—Sheet 3	749
N	Three Curve Series—Sheet 4	751
O	One Curve Series—Sheet 1—Water Level and Discharge Curves, Lake Erie and Niagara River	753
P	One Curve Series—Sheet 2	755
Q	One Curve Series—Sheet 3	757
R	Curves showing observed and computed Elevations, Lakes Michigan, Huron, Erie, Ontario (also Complainant's Exhibit "A")	759
S	Discharge Curve St. Lawrence River, Sherman Moore, 1912	761
T	Comparison of St. Lawrence (1912), Discharge with Niagara Discharge, Complainant's Equation	763
U1 U2 U3 U4 U5	A series of sheets of computations establishing the Increment of the Niagara River	765-769
V	Curves showing observed and computed Elevations of Niagara River by Chippawa Gage	771

DEFENDANT'S EXHIBITS IN SURREBUTTAL.

GEORGE M. WISNER'S EXHIBITS FOR DEFENDANT.

Number	Name	Page
7, 8, 9, 10, 11	Five (5) maps of the Chicago River from Lake Michigan through the main branch and south and west on the south branch to Ashland Avenue	733-781
12	Outline of Docks along Chicago River from 18th Street to Pennsylvania Railroad, prior to improvements	783
13	Same as Wisner Exhibit 12—Subsequent to improvement	785
14A	Curves of Flow at Power House and Controlling Works during Test of February 22 and 23, 1914	787
14B	Curves of Flow at Power House, Lemont, Summit and Dearborn Streets, Feb. 22, 23, 1914	788
14C	Water Levels in Main Channel and Chicago River, Feb. 22, 23, 1914	789

GEORGE M. WISNER'S EXHIBITS FOR DEFENDANT.

14D, E, & F.	Correspond to 14A, 14B and 14C for Test of March 8 and 9, 1914	790-792

GARDNER S. WILLIAMS' EXHIBITS FOR DEFENDANT.

36	Direction Measurements of Vertical Curves, International Bridge, Niagara River	793
37	Field Data on Vertical Curve, Span 6, Station 4/12 International Bridge	796
38	Plotting Vertical Curves, Niagara River, Sectional Oakfield, Vertical 8	797
39A, B	Plotting Hourly Water Levels, Buffalo and Chippawa, Nov., 1906	799, 801
39C, D	Table of Direction Measurements on Vertical Curves, Niagara River	802-805
39E1, E2, E3, E4	Plotting Buffalo Gage, Computed from Chippawa	807-813
40	Diagram giving analysis of method used for locating Direction Meter A, at tenths of depth	815
41	Discharge Measurements (Records), Niagara River (1907-1908)	817-821
42	Hourly Water Levels, Nov., 1906 (Table), Buffalo and Chippawa	822-829

VOL. VII.

SPECIAL CROSS INDEX OF U. S. EXHIBITS.

Page of printed record	Page of folio of exhibits	Description used in text of testimony	Description used in folio of exhibits	Page introduced	Remarks
7	49	Ex. 1, Feb. 15, '09	U. S. Ex. No. 1	7	Lowering Michigan-Huron
9	49	Ex. 1, Feb. 15, '09	U. S. Ex. No. 1		Lowering Michigan-Huron
10	51	Ex. 2, Feb. 15, '09	U. S. Ex. No. 2	10	Lowering St. L. R.
10	53	Ex. 3, Feb. 15, '09	U. S. Ex. No. 3	10	Lowering Lake Erie
10	55	Ex. 4, Feb. 15, '09	U. S. Ex. No. 4	10	Lowering Lake Erie

Subject	Page
Preface	1
Pleadings	2-94
Bill of Complaint, Calumet Suit	3
Exhibits to Bill of Complaint, Calumet Suit	6
Answer to Complaint, Calumet Suit	9-16
Exhibits to Answer	17
Complaint, Main Channel Suit	17-21
Exhibits, Bill of Complaint, Main Channel Suit	21-38
Answer, Main Channel Suit	39-68
Exhibits to Answer, Main Channel Suit	69-94
Opinions, Orders and Assignment of Errors	95-124
Opinion of Judge Landis	95-98
Motion for re-consideration of oral opinion and direction of Judge Landis	98-112
Exhibit to Motion	110-112
Order consolidating Causes	113
Opinion of Judge Carpenter	113-116
Order refusing offer of Sanitary District to construct certain works	116
Decree for Injunction	117
Petition for Appeal Allowed, and Injunction Suspended during its pendency	117
Assignment of Errors, filed June 29, 1923	118-123

Subject	Page
Evidence	124 et seq.
General Description of Evidence	124-126
Hydraulic Expert Evidence	126-145
Plaintiff's Hydraulic Expert Witnesses and their qualifications	127-131
Conclusions of Plaintiff's Hydraulic Experts	131-134
Defendant's Hydraulic Expert Witnesses and their qualifications	134-139
Description of the Great Lakes and Drainage Area, Run-off Causes of Changes in Levels	139
Great Lakes Surfaces higher during ten years subsequent to the opening of defendant's diversion canal than for the ten years prior	139
Amount of diversions between 1900 and 1913	139
Conclusions of Defendant's Hydraulic Expert Witnesses	139-142
Plaintiff's Hydraulic Expert Witnesses in rebuttal	142-144
Sur-rebuttal Hydraulic Expert Witnesses, testimony of defendant	145
Plaintiff's Evidence on Damage to Commerce	145-149
Defendant's Evidence on Damage to Commerce, assuming lowering of lake surfaces due to Chicago diversion	149-162
Affirmative undisputed Evidence of Defendant	163 et seq

PREFACE.

The record in this case contains a number of volumes, consisting of approximately 5,000 printed pages. It was considered advisable and proper, in connection with the presentation of this case, to prepare in condensed form a narrative statement of the pleadings and facts, to which reference could be made by both parties in preparing their respective briefs. Such of the facts as are contained in the record deemed to be material to either party to the suit are included in this statement. The facts bearing upon a particular subject have been drawn together in this statement and collected from different portions of the record, the record page where the matter may be found, being indicated. However, the submission of this statement shall not preclude reference to the record for any matter not contained herein.

IN THE

SUPREME COURT OF THE UNITED STATES.

OCTOBER TERM, A. D. 1924.

THE SANITARY DISTRICT OF CHICAGO, *Appellant,* *vs.* THE UNITED STATES OF AMERICA, *Appellee.*	Appeal from the District Court of the United States, for the Northern District of Illinois, Eastern Division.

APPELLANT'S NARRATIVE STATEMENT OF THE PLEADINGS, FACTS AND EVIDENCE.

There are two suits involved here. One bill of complaint was filed in the Circuit Court of the United States, for the Northern District of Illinois, Eastern Division, March 23, 1908, and involves the diversion of water from Lake Michigan through the Calumet River and the Calumet Sag Channel, an adjunct of the Main Channel of the Sanitary District, and will be called, for convenience, the Calumet Suit. In the second suit the complaint was filed October 6, 1913, in the District Court of the United States, for the Northern District of Illinois, Eastern Division, and involves the diversion of water through the Chicago River and the Main Channel of the Sanitary District, and all other diversion sources, including the Calumet River and Calumet Sag Channel.

PLEADINGS.

The bill of complaint in the Calumet suit, filed March 23, 1908, in the Circuit Court of the United States, for the Northern District of Illinois, alleged and set forth the following (Vol. VIII, pages 1 to 8, inclusive):

The complainant, The United States, was represented by Charles J. Bonaparte, attorney general, and Edwin W. Sims, District Attorney.

First. The Sanitary District is a municipal corporation, organized and existing under an act of the General Assembly of Illinois, approved May 29, 1889, in force July 1, 1889, and entitled: "An Act to create Sanitary Districts and to remove obstructions in the Desplaines and Illinois Rivers." Its principal office is Chicago, Illinois, and it is a citizen thereof.

Second. The Main Calumet River situated in, and flowing, in a northeasterly direction through, the County of Cook, in the said State of Illinois, and emptying into Lake Michigan at South Chicago, in said county, is a navigable river for its entire length from Lake Michigan to where it is formed by the Little and Grand Calumet Rivers. The United States has appropriated and expended large sums of money in improving the navigability of said river, and in improving the harbor at the mouth of the same, that is to say, it has appropriated and expended in such improvement of said river, including its tributaries in Indiana and Illinois, between the years 1884 and 1907, inclusive, the sum of $994,218.98, and in the improvement of said harbor since the year 1870, the sum of $1,567,230. At the present time the largest vessels on Lake Michigan can enter the said harbor and pass up said river for a distance of five miles, and small vessels can ascend the remaining three miles. The Little Calumet River, which, between the mouth of Stoney Creek and the mouth of said river, flows through the said County of Cook in an easterly direction, and in conjunction with the Grand Calumet River in said County, forms the said Calumet River, is also a navig-

able river from its month to the mouth of Stoney Creek in said County. For all of said distance it has a depth of about six feet and steamboats and sailing vessels engaged in interstate commerce use said river. The bridges across said river for said distance, are provided with draws for the accommodation of such craft, and such bridges are under the direct supervision of the Secretary of War of the said United States. The Grand Calumet River, an interstate stream rising in the State of Indiana and flowing in a northwesterly direction into and through the State of Illinois, to the said point of its conjunction with the Little Calumet River, is also a navigable river, and the United States has expended large sums of money in improving its navigability. Lake Michigan and its harbor and connecting rivers and channels, are navigable waters of the said United States. The United States has appropriated and expended large sums of money in improving the navigability of the rivers, channels and harbors connected with said Lake Michigan.

Third. On December 7, 1904, the Board of Trustees of the Sanitary District of Chicago, passed an ordinance, approved by its president, establishing and laying out a route for a channel and outlet of The Sanitary District of Chicago, to be known as the Calumet-Sag Channel. The said ordinance directed that said channel be constructed from a point on the main channel of The Sanitary District at or near Sag, Illinois, about eleven miles in a northerly direction up the said main channel from Lockport, to a point in said Little Calumet River at the mouth of Stoney Creek aforesaid, near the City of Blue Island, connecting the said Little Calumet River with the main channel of The Sanitary District. The said Calumet-Sag Channel was to be of such size, depth and slope that it would have a capacity of 4,000 cubic seconds feet of water, and thereby divert from Lake Michigan through it that amount of water, to the Desplaines, Illinois and Mississippi Rivers, and on to the Gulf of Mexico.

Fourth. On information and belief, it is stated that the diversion and abstraction of the waters of Lake Michigan

into the Mississippi River basin as aforesaid, will lower the level of the water in Lake Michigan, and thus diminish the navigable capacity and depth of the various rivers, channels and harbors connected therewith which have been deepened and improved at great expense under the authority of the Congress of the United States. The construction and maintenance of the Calumet-Sag Channel and the diversion and abstraction of the proposed amount of water from Lake Michigan will have a tendency to undo and annul the orders of Congress as expressed in the various river and harbor acts appropriating funds for improving the harbors and channels connecting with Lake Michigan. The construction and maintenance of said Calumet-Sag Channel as proposed, with its attendant diversion of waters of Lake Michigan, will alter and modify the condition and capacity of all the said harbors and of all the said channels (navigable waters of the United States), and will impede, injure and obstruct navigation in many of said harbors and channels, and will create an obstruction to the navigable capacity of the said mentioned waters of the said United States.

Fifth. For the diversion of said water and the creation of said obstruction to the navigable capacity of said navigable waters of the United States by the defendant, The Sanitary District of Chicago, has not been and is not affirmatively authorized by the Congress of the United States, and has not been and is not authorized in any way by said Congress.

Sixth. The construction and maintenance of the Calumet-Sag Channel as proposed, will lower the levels of the water in the Calumet, the Little Calumet and Grand Calumet Rivers, and will alter and modify the course, condition and capacity of those rivers, respectively.

Seventh. The proposed Calumet-Sag Channel with its attendant diversion, will lower the levels of the waters of Lake Michigan, and will injure and impede navigation in all the harbors and channels in said waters.

Eighth. Section 10 of the Rivers and Harbors Act of March 3, 1899, has remained in force and effect ever since its passage.

Ninth. About November 28, 1906, defendant applied to the Secretary of War for authority to construct and maintain said Calumet-Sag Channel, and to reverse the flow of the Calumet Rivers. Thereupon the Secretary of War requested the Chief of Engineers to make his recommendation concerning the said application. February 23, 1907, the Chief of Engineers reported that he was unwilling to recommend favorably. On March 14, 1907, the Secretary of War denied the application for the said work, and up to the present time the said work has not been recommended by the Chief of Engi neers and has not been authorized by the Secretary of War, and is otherwise without the authority, permission and approval of the said Secretary of War.

Tenth. Defendant, The Sanitary District of Chicago, has announced its intention to construct and maintain said Calumet-Sag Channel, reverse the flow of the Calumet Rivers, and divert water from Lake Michigan. The defendant's board of trustees, on September 18, 1907, adopted and passed an ordinance providing for the construction of said channel, and announcing defendant's intention to construct same, which is marked Exhibit A to the bill of complaint.

(All exhibits to pleadings and documents quoted therein were either offered in evidence or admitted by the pleadings.)

Eleventh. Defendant proposes to divert water from Lake Michigan through the said Calumet Rivers and Calumet-Sag Channel, for sanitary purposes, and for the development of water power. Congress has not fixed any amount of such water for such proposed diversion, and has not provided for same, nor has the Secretary of War, under congressional direction, fixed any amount of such water for such proposed diversion. On the contrary, the Secretary of War has refused to authorize same.

Twelth. Defendant cannot lawfully construct or maintain said Calumet-Sag Channel or reverse the flow of the Calumet Rivers or divert the water from Lake Michigan as proposed.

Thirteenth. October 16, 1907, defendant commenced the excavation of said Calumet-Sag Channel, and defendant intends to and will continue and complete the construction of said channel, reverse the flow of the Calumet River, divert waters from Lake Michigan as proposed, to the irreparable injury of complainant and its interstate navigation and commerce, unless restrained by injunction.

Prayer of bill.

Defendant be restrained and enjoined from beginning or attempting to construct or continuing the construction of, and from doing anything in, towards, or about, the construction of said proposed Calumet-Sag Channel, or diverting or abstracting any waters from Lake Michigan, or from doing or attempting anything in any way to connect the waters of the Calumet Rivers with the main channel of the Sanitary District, from doing or attempting anything in any way to reverse the flow of the Calumet Rivers, and from doing or attempting anything in any way to divert or abstract any waters from Lake Michigan in any channel other than the Chicago River as already authorized by the Secretary of War, unless prior to beginning any of said work or doing or attempting to do any of such things, the Chief of Engineers of the United States shall have recommended, and the Secretary of War of the United States shall have authorized, the doing of such work.

Exhibit A to the bill of complaint.—Ordinance passed by the Board of Trustees of the Sanitary District of Chicago on September 18, 1907.

Whereas, on December 7, 1904, by an ordinance passed by the board and approved by the president, the board established and laid out a route for a channel and outlet of The Sanitary District of Chicago, which channel was by said

ordinance to be constructed and maintained, together with the necessary additions thereto, within the limits of said route;

Whereas, by the terms of said ordinance, it is provided that a channel be constructed by The Sanitary District of Chicago, as described in the bill of complaint;

Whereas, the construction and maintenance of the channel provided for will result in diverting and reversing the flow of the Calumet River, a navigable stream now flowing into Lake Michigan;

Whereas, heretofore, to wit, on November 28, 1906, this board instructed its president to transmit to the Secretary of War an application for a permit to reverse the flow of said Calumet River and thereafter, to wit, on March 14, 1907, the Secretary of War communicated to the board his refusal to issue such permit;

Whereas, this board is advised that it has the right and that it is the duty under the laws of the State of Illinois, to construct said channel, nothwithstanding the refusal of the Secretary of War to issue a permit therefor, for the purpose of furnishing the proper sanitary method of disposing of the sewage of the territory and inhabitants contiguous to the said proposed channel and within the corporate limits of The Sanitary District of Chicago, and unless restrained by a court having jurisdiction of the subject matter at the instance of the United States Government; and

Whereas, the Board of Trustees of the Sanitary District of Chicago deemed the construction of such channel and the reversal of the flow of said Calumet River necessary for the preservation of the health of persons within the limits of the Sanitary District, and that it is in duty bound to proceed with the construction thereof, first giving notice of its intention so to do to the Secretary of War and to the Attorney General, that they may, if they see fit, take such steps as they think proper to protect the rights, if any, of the general government—

Ordered by the Board of Trustees of The Sanitary District of Chicago, as follows:

First. Finance committee to arrange for the purchase of right of way.

Second. Chief Engineer to prepare plans and specifications for the construction of said channel according to the terms of the ordinance adopted by the board December 7, 1904.

Third. The clerk of the district is directed to transmit a certified copy to the Secretary of War, Attorney General, Chief of Engineers, and District Engineer in charge at Chicago.

Answer of the Sanitary District of Chicago to the bill of complaint filed March 23, 1908, as follows: (Vol. VIII, pages 9 to 28.)

First. Admits it is a municipal corporation, as alleged in the bill of complaint. Map is attached as Exhibit A to the answer, showing the territorial limits of The Sanitary District of Chicago, comprising 358 square miles, located within which there are a number of cities, towns and villages, including Chicago.

Second. Admits the allegations of the bill of complaint as to the location of the Calumet River, but denies that it is a navigable river, and that it is traversed by vessels engaged in commerce; admits the allegations of Paragraph 2 of the bill of complaint as to the amount of moneys appropriated and expended by the Federal Government in the improvement of said river, but denies that the Calumet River, from its mouth to the conjunction with Stoney Creek, is a navigable river, and that it is traversed by the vessels engaged in interstate or intrastate commerce; that the Grand Calumet River from its origin in the State of Indiana to its confluence with the Little Calumet River, is a navigable river.

Third. Admits the passage of the ordinance of December 7, 1904, laying out the said Calumet-Sag Channel; a copy of said ordinance is attached, marked Exhibit G.

Avers that on January 22, 1908, the Board of Trustees of defendant passed another ordinance extending the right of way, laid out by ordinance of December 7, 1904, in an easterly direction to a point known as "Forks," as shown on Exhibit F attached; copy of said ordinance is attached as Exhibit H.

Denies that the construction of said channel as proposed will result in diverting and abstracting from Lake Michigan, 4,000 cubic feet of water per second.

Fourth. Denies that the diversion and abstraction of waters from Lake Michigan contemplated through the Calumet-Sag Channel, will lower the level of the water of the Great Lakes, and will diminish the navigable capacity of said waters or the harbors thereof.

Denies that interstate or any other commerce will be injured or interfered with by said diversion, or by the maintenance of said Calumet-Sag Channel; that the construction of said channel will have a tendancy to undo orders of Congress; that the construction of said channel will alter and modify the conditions of the rivers and harbors of the United States, or any of them, and substanially and seriously impede, injure and obstruct navigation of the Great Lakes. Avers that construction and maintenance of said waterway and channel, with its attendant diversions, will not in any wise affect the navigable capacity of the Great Lakes or the harbors and channels connected therewith, or the rivers flowing into same, and will not injure commerce; that the said channel and its operation and maintenance will be to the interest of interstate commerce.

Fifth. Denies the allegation to the effect that the said construction of the said Calumet-Sag Channel had not been affirmatively authorized by Congress. Avers that it has been expressly authorized.

Sixth. Denies that the construction and maintenance of said channel will lower the level of the Little Calumet River.

Seventh. Admits that the bodies of water mentioned in paragraph 7 of the bill of complaint, are each connected with the other, and are in a measure inter-dependent upon each other for the respective water levels. Denies that the said proposed channel would lower the levels of all of said waters, or any of them, or that it would injure or impede navigation in such harbors and channels.

Eighth. Admits Section 10 of the Rivers and Harbors Act of March 3, 1899, has been and is in full force and effect. Denies that said act has any binding force on the defendant, or prohibits the construction and maintenance of said channel, or that the same is a constitutional or valid enactment.

Ninth. Admits application November 28, 1906, to the Secretary of War for permit to reverse the flow of the Calumet River; denies that by making said application, it admitted the jurisdiction of the Secretary of War in such matters, that it required such permit. Avers that it made such application as a matter of comity and in order to promote and maintain the spirit of harmony which it believes should obtain between the Federal Government and the various state and local governments; all of which is shown by statement filed with the Secretary of War at the time of making said application—

> "That while insisting upon the right as a matter of right, we are entitled, nevertheless, to a permit from the Secretary of War; to evidence that there exists between the two governments that 'spirit of harmony and conciliation' which, in the words of Chief Justice Marshall, in *Gibbons* v. *Ogden* (9 Wheaton, 1), 'ought always to characterize the conduct of governments standing in the relation which that of the Union and those of the states bear to each other'; and to further evidence on the part of said governments that 'frank and candid cooperation for the general good' spoken of by Justice Johnson in the same case, ' which should always take place where there is a seeming blending of the power of the two governments and an apparent conflict'!"

Tenth. Admits that defendant has announced its intention to proceed to construct said Calumet-Sag Channel.

Eleventh. Admits Section 1 of Act of Congress approved June 29, 1906.

Twelfth. Denies the allegation of the bill of complaint to the effect that Congress has not provided for the diversion of any of the waters of Lake Michigan through said channel. Avers that the defendant and the State of Illinois are expressly authorized by congressional legislation to construct and maintain a waterway such as is proposed by the defendant and to divert the waters of Lake Michigan through the same into the Illinois River.

Thirteenth. Denies that defendant cannot lawfully construct and maintain said proposed channel. Avers that it is lawfully empowered to do so and that it is the duty under the laws of the United States and of Illinois.

Fourteenth. Admits that on October 16, 1907, it began work on said channel; that it proposes to construct the same in the manner and form and of the character, size and dimensions as hereinafter set forth. Denies that the construction and maintenance thereof would be to the manifest or irreparable injury of the United States or to interstate and foreign commerce. Avers that the waterway will benefit both state and interstate commerce.

Fifteenth. Avers that in 1822 and 1827 Congress enacted laws authorizing Illinois to construct a waterway suitable for navigation, connecting the waters of Lake Michigan with those of the Illinois River, and to thereafter maintain the same at all times in a condition suitable for navigation, as will more fully appear from the said acts, to which reference is made; that after the passage of said acts, the State accepted same and thereafter, by various acts duly passed by the General Assembly of Illinois, approved by the Governor, the State authorized the construction of and did construct and has ever since maintained, a waterway connecting the waters of Lake

Michigan with those of Illinois River over and through which waterway commerce has been carried on continuously since the date of the completion thereof in, to wit, 1848. Defendant refers to each and all of the several acts of Illinois legislature relating to said waterway. Avers that the waterway as originally constructed, connected the waters of Lake Michigan with those of the Illinois River by a channel terminating at or near the City of Peru, on the Illinois River, in the County of LaSalle, Illinois, and beginning at a point on the Chicago River which in turn connected with Lake Michigan, in the City of Chicago, and also by a branch terminating at or near the mouth of Stony Creek on the Calumet River, which said channel and which said branch connecting with said Calumet River, are represented and shown, by lines colored yellow, on the map or plat which is hereto attached, marked Exhibit E.

Sixteenth. Avers that the defendant, in compliance with and pursuant to the powers and duties resting upon it, constructed a channel of the character, size and dimensions provided for by the original act of its incorporation, extending from a point on the Chicago River in the City of Chicago near the original termination of the Illinois and Michigan Canal, parallel with said Illinois and Michigan Canal, to and through the City of Joliet, as shown upon Exhibit E to the answer; that the construction of said channel was begun in the year 1892; that said channel was completed from its said connection with the Chicago River to a point at or near Lockport, a distance of three or four miles northeasterly from the City of Joliet, in the year 1900, sufficiently to turn the waters therein for the purpose for which said canal had been constructed; that in the year 1900, pursuant to various laws of the State and of the United States, defendant did divert waters of said Chicago River and Lake Michigan to and into said waterway and discharged the same into the Desplaines and thence into the Illinois River; that since the turning in of said waters defendant has prosecuted the work of extending said canal through the City of Joliet, and has likewise

continued the work of deepening and widening the Chicago River with which it connects, for the purpose of making said waterway sufficient to accomplish the objects of its creation, both as an outlet for the sewage of The Sanitary District and for the purpose of commerce and navigation; that said waterway or channel has been substanially completed from the Chicago River to the City of Joliet, a distance of thirty-two miles; that at Lockport there is a lock 130 feet long and 22 feet wide and 12 feet over-mitre sills; that alongside this lock, there is a reservation for a lock of ample capacity to accommodate the largest lake-going vessels; that upon the construction of the large lock, the largest lake-going vessels will be able to pass through this channel from Lake Michigan to the City of Joliet; that defendant has expended in the construction and operation of said waterway to September 1, 1907, $54,500,000, which sum, added to that spent by the State of Illinois on the Illinois and Michigan Canal, equals $61,037,254.79.

Seventeenth. Avers that after the turning in of the water into said waterway already constructed by defendant, the City of Chicago, lying wholly within the confines of the territorial limits of the defendant, has so reconstructed and built its sewage system, by a system of intercepting sewers and trunk sewers, as to carry the sewage of that portion of said city north of Eighty-seventh street and south of Fullerton avenue into said channel, thus preventing the discharge thereof into Lake Michigan as it theretofore existed. That thereby the city has prevented the pollution of Lake Michigan and partially protected the water supply of said city procured from the lake through water tunnels and intakes. That the location of the intakes is indicated upon Exhibits A and D to the answer. That the territory of the City of Chicago discharging into the defendant's channel and waterway, is represented upon Exhibit B: That the City of Chicago has constructed a trunk sewer or conduit from a point near the intersection of the shore line of the lake with Thirty-ninth street westward to the south fork of the south branch through which

said trunk sewer or conduit water from Lake Michigan is pumped, and it has a maximum capacity of 120,000 cubic feet per minute.

Eighteenth. Avers that the sewage from that portion of defendant's territory lying south of Eighty-seventh street, still discharges into Lake Michigan either directly or through the Calumet River, and pollutes the waters of the lake, and is a constant menace to the people as it contaminates the water in proximity to and around and about the Hyde Park or Sixty-eighth street intake, through which a large portion of the water supply of the inhabitants of the city passes, and through which other muicipalities within the defendant's limits obtain their water. That the water mains of the City of Chicago are so interdependent that the water entering any of same may find its way into any and all portions of said city, and that the pollution of any one of the intakes of said city does or may pollute the water supply of said entire city and in this manner menaces and threatens the health and welfare of all of the people of said community; that there is being discharged into said Lake Michigan the sewage of substantially 200,000 people residing south of Eighty-seventh street.

Nineteenth. Avers that waterway and channel sought to be enjoined is for the purpose of protecting the water supply of inhabitants south of Eighty-seventh street, and in compliance with the duty prescribed by the several laws of Illinois; that when completed, it will be located as represented and shown on Exhibits B and C, substantially twenty-one miles in length from the eastern shore line of Lake Calumet to the connection thereof with the main channel at Sag, Illinois. That from Lake Calumet, the channel will extend along the little Calumet River to Blue Island; thence sixteen miles to Sag, Illinois. That the Calumet River will be dredged to a depth of twelve feet, with a bottom width of seventy-two feet and water line width of 160 feet; that the channel itself will have a width in the glacial section of seventy-two feet

and 162 feet at the water surface, with a depth of twenty-two feet; in the rock sections ninety-three feet with vertical sides and depth of twenty-two feet.

Twentieth. Avers that defendant proposes to flow westwardly through said channels, water sufficient to reverse the flow of the Calumet River in order to carry the sewage discharging therein away from Lake Michigan; that the quantity of water so diverted would only be sufficient to cause a reversal of said flow and to properly dilute the sewage so as to comply with the several laws under which the defendant is incorporated, not exceeding at any time 4,000 cubic feet per second; that the maximum amount of water that can be flowed through the main channel of the defendant westwardly from the confluence of the Calumet-Sag Channel with it, is 840,000 cubic feet per minute; that the amount of water the defendant will flow through said channel from time to time, will only be such amount as is required by law for the proper dilution of sewage of the district; that by the construction and maintenance of the proposed Calumet-Sag Channel, it is not proposed to flow any more water than sufficient to meet the requirements of law for sewage dilution, which amount it would be bound by law to flow through its main channel without the construction of the Calumet-Sag Channel complained of.

Twenty-first. Denies that the construction and maintenance of the proposed channel will in any wise affect the levels of the Great Lakes and their connecting waters, or that it will injure or be a detriment to commerce thereon, or that it will affect the navigable capacity of the Little Calumet or Grand Calumet Rivers. Avers that it will not in any wise affect, alter, modify or change the Little Calumet River other than as herein specifically set forth, which is to the benefit of said river and commerce thereon.

Twenty-second. Avers that Exhibit F attached, shows in detail the dimensions of the Calumet and Little Calumet Rivers from Lake Michigan to Stony Creek; that the Calumet River to the eastern terminus of defendant's Calumet-Sag Channel, has a depth twenty-two, twenty-one and seven-

teen feet; that from the easterly terminus of defendant's proposed channel along and in the Calumet River, the present depths of the river are from eight to four feet, and it is correspondingly narrow.

Twenty-third. Avers that upon the completion of the Calumet-Sag Channel as proposed, it will afford navigation for vessels of the Great Lakes through the Calumet River to its main channel, and from thence to the City of Joliet, and will be a sufficient and valuable route for commerce, and will be for the benefit of commerce on the Great Lakes, Desplaines, Illinois and Mississippi Rivers; that all the water proposed to be diverted through its main channel and the Calumet-Sag Channel, will be discharged into the Desplaines River, and from thence into the Illinois River, and will form, through and by said rivers, a navigable channel from Lake Michigan to the Mississippi River; that the construction and maintenance of said Calumet-Sag Channel and said main channel through and by the authority of the State, is in accordance with the declared and express public policy of the United States and the State of Illinois to forever maintain a waterway suitable for navigation connecting the waters of Lake Michigan with the waters of the Illinois and Mississippi Rivers.

Twenty-fourth. Avers that defendant is the only body or municipality clothed with authority to provide for the drainage and disposal of sewage in furnishing the outlets therefor within its corporate limits; that by reason of the laws of Illinois, it is proceeding to dispose of and provide a means for disposal of, by a channel and adjuncts thereto, of all the sewage arising within its corporate limits which would otherwise flow into Lake Michigan, polluting the water supply of the inhabitants of defendant; that there is no other lawful method provided of disposing of the sewage and drainage of said territory, than by the construction of channels and adjuncts thereto, and that said proposed Calumet-Sag Channel is part of the only plan provided for the disposal of sewage and the furnishing of outlets therefor.

Exhibit G to answer, being an ordinance adopted December 7, 1904, by the Board of Trustees of the Sanitary District, laying out and adopting the project of the Calumet-Sag Channel. (Vol. VIII, Pages 19 to 26.)

The ordinance lays out the route of the Calumet-Sag Channel, describes by legal description the properties through and over which it passes, locates the center line as extending from the main channel of the Sanitary District near Sag, Illinois, easterly to a point at Stony Creek, near Blue Island, Illinois. (Exhibits A, C, D, E, F, page opposite.)

Exhibit H to answer, being ordinance passed January 22, 1908, supplementary to the ordinance of December 7, 1904, extending the right of way of the Calumet-Sag Channel easterly through Blue Island, to a point on the Little Calumet River. (Vol. VIII, Pages 26-28.)

Complaint in Main Channel suit, filed October 6, 1913. (Vol. VIII, pp. 39-58.)

The United States was represented by James G. McReynolds, Attorney General, and James H. Wilkerson, United States District Attorney for the Northern District of Illinois, against the Sanitary District of Chicago, and the complaint alleges the following:

First. Defendant, the Sanitary District of Chicago, is a municipal corporation, organized under an act of the General Assembly, approved May 29, 1889, in force July 1, 1889, and entitled: "An Act to create Sanitary Districts and to remove obstructions in the Desplaines and Illinois Rivers." Its principal place of business is Chicago, Illinois, and it is a citizen of said state.

Second. The Chicago River is situated in Cook County, Illinois, and consists of a main river, originally flowing in a generally easterly direction emptying into Lake Michigan. The said river was formed by two branches known as the

north and south branches, the south branch being divided into two forks, known as the west fork and the south fork.

Third. The Chicago River, including the north and south branches, west and south fork of the south branch, is a navigable water of the United States.

Fourth. The United States has appropriated and expended $4,216,066.36 in improving the said river and harbor at the mouth of the same.

Fifth. Section 10 of the act of Congress approved March 3, 1899, known as the Rivers and Harbors Act of that year has remained in full force and effect ever since its passage.

Sixth. Prior to May 8, 1899, the Sanitary District applied to the Secretary of War for permission to reverse the current and flow of the Chicago River and divert and abstract a quantity of water from Lake Michigan through said Chicago River and through a certain canal which was constructed by defendant. On May 8, 1899, the Secretary of War issued a permit to the defendant to reverse the current and flow of said river and to divert and abstract from Lake Michigan, not to exceed 300,000 cubic feet per minute, reserving the right to make changes as the Secretary of War should see fit in the interests of navigation and property rights. Copy of said permit is attached as "Exhibit A."

Seventh. April 9, 1901, the Secretary of War ordered defendant to reduce the flow through the Chicago River to 200,000 cubic feet per minute. Copy of the order is attached as "Exhibit B."

Eighth. Thereafter, the Secretary of War, pursuant to application of the Sanitary District of July 23, 1901, modified the preceding permit and order, and issued a permit to defendant to flow 300,000 cubic feet of water per minute, between the hours of 4:00 P. M. and 12:00 P. M. midnight, copy of which order or permit is attached as "Exhibit C."

Ninth. Subsequently, pursuant to application of the Sanitary District, on the 5th of December, 1901, the Secretary of War issued a permit to flow 250,000 cubic feet per minute throughout the twenty-four hours of the day, copy of which is attached as "Exhibit D."

Tenth. Thereafter, on the 17th day of January, 1903, a permit was issued to the Sanitary District to increase the flow to 350,000 cubic feet per minute until March 30, 1903, after which date the flow was to be reduced to 250,000 cubic feet per minute, as theretofore, copy of which is marked "Exhibit E" and attached.

Eleventh. On November 28, 1906, defendant made application to the Secretary of War for permission to construct a canal connecting the Calumet River with the main channel of the Sanitary District Canal at what is known as Sag, Illinois, and to reverse the flow of the Calumet River, which application was refused March 14, 1907, by the Secretary of War.

Twelfth. On the 11th of September, 1907, permit was granted pursuant to application of the Sanitary District to construct a canal connecting Lake Michigan at Wilmette, Illinois, with the north branch of the Chicago River, upon condition that the total diversion of water from Lake Michigan through the Chicago River should not exceed the amount already authorized by the War Department, to wit, 250,000 cubic feet per minute.

Thirteenth. Subsequently, pursuant to application of the Sanitary District of June 27, 1910, a permit was granted by the Secretary of War, authorizing defendant to construct a canal connecting the Calumet River with the main channel of the Drainage Canal at Sag, Illinois, and to divert and abstract water from Lake Michigan through said canal, providing, among other things, that the amount of water withdraw from Lake Michigan through the Chicago River should not exceed the total amount of 250,000 cubic feet per minute, the amount previously authorized to de withdrawn.

Fourteenth. February 5, 1912, defendant applied to the Secretary of War for permission to withdraw and divert from Lake Michigan, through the Chicago River and Calumet River, not to exceed 10,000 cubic feet of water per second. Copy of the application is attached as "Exhibit F."

Fifteenth. January 8, 1913, the Secretary of War refused the application of February 5, 1912, copy of which refusal is attached as "Exhibit G."

Sixteenth. Defendant has for a long period of time abstracted water from Lake Michigan, caused it to flow through the Chicago River, and is at present diverting through said river, from 400,000 to 600,000 cubic feet per minute, which amount is greatly in excess of the amount permitted by the Secretary of War, and is in violation of the permits of said Secretary of War, which limit the flow to 250,000 cubic feet per minute. Defendant intends and threatens to continue.

Seventeenth. Congress has not authorized the diversion through the Chicago River, and the Chief of Engineers has not recommended in excess of 250,000 cubic feet per minute.

Eighteenth. Diversion and abstraction of water in excess of 250,000 cubic feet per minute, has lowered and will continue to lower the level of the water of Lakes Michigan, Huron, St. Clair, Erie, Ontario, and the Rivers Sault Ste. Marie, St. Mary's, St. Clair, Detroit, Niagara, St. Lawrence, and all the harbors, canals, channels and rivers connected therewith, all being navigable waters of the United States, and will thus injure and diminish and create obstructions to the navigable capacity of all said waters.

Nineteenth. Said waters have been deepened and improved at great expense under congressional authority. The diversion and abstraction of waters from Lake Michigan in excess of the permits hereinabove set forth, will have a tendency to undo and annul the orders of Congress as expressed in the various Rivers and Harbors acts appropriating funds for im-

proving harbors and channels in the above named waters and channels connected therewith.

Twentieth. The diversion of waters of Lake Michigan through the Chicago River, in excess of the permits, will alter and modify the condition and capacity of the channel of the said Chicago River, which is a channel of a navigable water of the United States.

Twenty-first. The diversion of the waters of Lake Michigan through the Chicago River in excess of the permits, will alter and modify the condition and capacity of Lakes Michigan, Huron, St. Clair, Erie, Ontario, the Rivers Sault Ste. Marie, St. Mary's, St. Clair, Detroit, Niagara and St. Lawrence, and the ports, roadsteads, havens, harbors, canals and harbors of refuge connected with the above named waters.

Twenty-second. Defendant cannot lawfully continue to divert and abstract water, in excess of the permits, as it is doing and threatens to do, without the recommendation of the Chief of Engineers and permission of the Secretary of War.

Prayer—That defendant be enjoined from diverting or abstracting any waters from Lake Michigan over, above and in excess of 250,000 cubic feet per minute, as already authorized by the Secretary of War.

Exhibit "A" to Bill of Complaint.

(Vol. VIII, Page 44.)

"Whereas, by Section 10 of an act of Congress approved March 3, 1899, entitled 'An act making appropriations for the construction repair and preservation of certain public works, on rivers and harbors, and for other purposes,' it is provided that it shall not be lawful to alter or modify the course, location, condition or capacity of the channel of any navigable water of the United States unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same:

And whereas, the Sanitary District of Chicago, a m
nicipal corporation, organized under the laws of the St
of Illinois, has constructed an artificial channel fr
Robey street, Chicago, to Lockport, and has been here
fore granted permission by the Secretary of War
make certain improvements in the Chicago river for
purpose of correcting and regulating the cross sectio
the river so as to secure a flowage capacity of 300,
cubic feet per minute with a velocity of one and one-qu
ter miles an hour, it being intended to connect the s
artificial channel with the west fork of the south bra
of Chicago river at Robey street in the City of Chic

And whereas, The said Sanitary District of Chic
has now applied to the Secretary of War for permis
to divert the waters of the said Chicago river and ca
them to flow into the said artificial channel at Ro
street as aforesaid;

And whereas, The said Sanitary District of Chic
represents that such movable dams and sluice gate
are necessary to, at all times, secure absolute and c
plete control of the volume and velocity of flow thro
the Chicago river have been constructed;

Now, therefore, The Chief of Engineers having
sented thereto, this is to certify that the Secretar
War hereby gives permission to the said Sanitary
trict of Chicago to open the channel constructed
cause the water of Chicago river to flow into the s
subject to the following conditions:

1. That it be distinctly understood that it is the in
tion of the Secretary of War to submit the questions
nected with the work of the Sanitary District of Chi
to Congress for consideration and final action, and
this permit shall be subject to such action as ma
taken by Congress.

2. That if, at any time, it becomes apparent that
current created by such drainage works in the south
main branches of Chicago river, be unreasonably
structive to navigation or injurious to property, the
retary of War reserves the right to close said disch
through said channel or to modify it to such exte
may be demanded by navigation and property inte
along said Chicago river and its south branch.

3. The the Sanitary District of Chicago must as
all responsibility for damages to property and na

tion interests by reason of the introduction of a current in Chicago river.

Witness my hand this 8th day of May, 1899.

R. A. Alger, Secretary of War. (Seal War Office.)
John M. Wilson, Brig. Genl. Chf. of Engrs.
U. S. A."

Exhibit "B" to Bill of Complaint.

"Whereas, under date of May 8th, 1899, the Secretary of War granted permission unto The Sanitary District of Chicago to open the artificial channel from Robey street, Chicago, to Lockport, and cause the waters of Chicago river to flow into the same, upon the following condition, *inter alia*:

(2) That if, at any time, it becomes apparent that the current created by such drainage works in the south and main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its south branch.

And whereas, It is alleged by various commercial and navigation interests that the present discharge from the river into the Drainage Canal sometimes exceeds three hundred thousand (300,000) cubic feet per minute, causing a velocity of nearly three (3) miles per hour, which greatly endangers navigation, in the present condition of the river.

Now, therefore, This is to certify that the Secretary of War, upon the recommendation of the Chief of Engineers, hereby directs said Sanitary District to regulate the discharge from the river into the Drainage Canal so that the maximum flow through the Chicago river and its south branch shall not exceed two hundred thousand (200,000) cubic feet per minute.

Witness my hand this ninth day of April, 1901.

Elihu Root, Secretary of War."

Exhibit "C" to Bill of Complaint.

"War Department, Washington

July 23, 1901.

SIR: Referring to War Department order of April 9th last, restricting the flow of water through the Chicago River under War Department permit of May 8, 1899 to 200,000 cubic feet per minute, and replying to your letter of the 15th instant, in which you request, for reasons stated, that the said order be amended to permit a flow of 300,000 cubic feet per minute between the hours of 4 P. M. and twelve o'clock midnight, I beg to inform you that I have this day approved the modification last referred to, which approval will be subject to revocation by the Department in case the increase shall prove to be dangerous to navigation.

Very respectfully, Elihu Root, Secretary of War.

Mr. Axelander J. Jones, President Sanitary District of Chicago, Chicago, Illinois."

Exhibit "D" to Bill of Complaint.

Whereas, Under date of May 8th, 1899, the Secretary of War granted permission unto the Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of Chicago River to flow into the same, upon the following condition, *inter alia*:

(2) That if, at any time, it becomes apparent that the current created by such drainage works in the South and Main Branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch;"

And whereas, The Secretary of War subsequently directed said Sanitary District of Chicago, to regulate the discharge of water into the Chicago Drainage Canal so that the maximum flow through the Chicago River shall not exceed 200,000 cubic feet per minute from midnight to 4 p. m., nor 300,000 cubic feet per minute from 4 p. m. to midnight;

And whereas, Said Sanitary District of Chicago has applied to the Secretary of War for permission to increase the flow between midnight and 4 p. m., daily, to 250,000 cubic feet per minute; and the Chief of Engineers has recommended that the increase applied for be granted, but that the rate of flow from 4 p. m. to midnight be reduced to 250,000 cubic feet per minute, so that the flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day.

Now, therefore, This is to certify that, in acordance with the recommendation of the Chief of Engineers, the Secretary of War hereby gives unto the said Sanitary District of Chicago permission to regulate said discharge so that the maximum flow through the Chicago River shall not exceed 250,000 cubic feet per minute throughout the 24 hours of the day, upon the following conditions:

(1). That this permission shall be in lieu of the present authorized rates of flow as stated above.

(2). That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

(3). That said Sanitary District of Chicago shall be responsible for all damages inflicted upon navigation interests by reason of the increase in flow herein authorized.

Witness my hand this 5th day of December, 1901.

W. Cary Sanger, Assistant Secretary of War."

Exhibit "E" to Bill of Complaint.

Whereas, under date of December 5, 1901, by an instrument supplementary to the original permission granted by the Secretary of War, May 8, 1899, to the Sanitary District of Chicago to open the artificial channel from Robey Street, Chicago, to Lockport, and cause the waters of the Chicago River to flow into the same, the Secretary of War, pursuant to authority reserved in said permission of May 8, 1899, gave permission to the Sanitary District of Chicago to regulate said discharge so that the maximum flow per minute throughout the twenty-four hours of the day, upon the following conditions *inter alia*:

'That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require;'

And whereas, The said Sanitary District of Chicago has applied for permission to increase the flow through the Chicago River from 250,000 cubic feet per minute to 350,000 cubic feet per minute during the closed season of navigation, in order to carry off the accumulations of sewage deposit which line the shores along the city;

Now, therefore, This is to certify that, in accordance with the recommendation of the Chief of Engineers, the Secretary of War hereby gives unto said Sanitary District of Chicago permission to increase the flow through the Chicago River from 250,00 cubic feet per minute to 350,000 cubic feet per minute, until the 31st day of March, 1903, after which date it shall be reduced to 250,000 cubic feet per minute, as now authorized, upon the following conditions:

(1) That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

(2) That said Sanitary District of Chicago shall be responsible for all damages inflicted upon navigation interests by reason of the increase in flow herein authorized.

Witness my hand this seventeenth day of January, 1903.

W. Cary Sanger, Assistant Secretary of War."

Exhibit "F" to Bill of Complaint.

"The Sanitary District of Chicago

Chicago, February 5th, 1912.

SIR: On behalf of the Board of Trustees of The Sanitary District of Chicago, I have the honor to apply for enlargement of the terms of an instrument executed by The Secretary of War May 8, 1899, as modified by instruments similarly executed on December 5, 1901, and June 30, 1910, respectively, in the following particulars and in view of the facts hereinafter set forth, to wit:

The flow of water from Lake Michigan through the canal of The Sanitary District of Chicago is now limited by the said instruments to 4167 cubic feet per second.

The population of the Sanitary District, the sewage of which is to be disposed of through the channels constructed and to be constructed by the said District, exceeds 2,500,000 persons, and is rapidly increasing. The only method at present available for disposing of the sewage of this population is by diluting the same with water withdrawn from Lake Michigan and flowing through the Chicago Drainage Canal. The least amount of water necessary to render sewage innocuous by the dilution method has been estimated by well recognized sanitary experts as 1,000 feet per second for every 300,000 inhabitants; so that the amount permitted to be withdrawn by the instruments to which reference has been made is much below the amount at present needed by the District.

The Sanitary District has been for some time engaged in investigating methods and devising plans for the treatment of the sewage with a view to requiring less water for its safe dilution in the future. The methods of other states and countries for such treatment of sewage, are not as yet entirely satisfactory to all concerned, and any changes of methods for large cities must necessarily require several years.

Until these experiments are concluded and proper works installed, the use of additional water from Lake Michigan is essential to the health of the large population of the City of Chicago and of the Sanitary District and of those who live adjacent to the Des Plaines and Illinois rivers into which such waters are discharged.

Subject therefore to such restrictions as to you may seem proper for the protection of the public interest, and to such a method of supervision as you may suggest to promote the general welfare, and pending the completion of the investigations now being conducted to render the use of increasing quantities of water in the future necessary; I have the honor to apply for permission for The Sanitary District of Chicago to withdraw from Lake Michigan through the Chicago river and Calumet river—not to exceed ten thousand cubic feet of water per second; such permission to be revocable at any time by The Secretary of War, and subject to such action as the Congress of the United States may see fit to take in the premises.

Respectfully submitted, George M. Wisner, Chief Engineer. Hon. Henry L. Stimson, Secretary of War, Washington, D. C."

Exhibit "G" to Bill of Complaint.

"In the matter of the Application of THE TRUSTEES OF THE SANITARY DISTRICT OF CHICAGO for Permission to Divert from Lake Michigan 10,000 Cubic Feet of Water Per Second.

War Department

Washington, January 8, 1913.

The Sanitary District of Chicago applies to the War Department for permission to increase the amount of water it is authorized to withdraw from Lake Michigan from 4,167 cubic feet per second, the amount now authorized, to 10,000 cubic feet per second.

The Chicago Drainage Canal was opened in January, 1900. It reversed the flow of the Chicago River, which formerly emptied into Lake Michigan, and as a result a portion of the waters of that lake, instead of following their former course through Lakes Huron, Erie and Ontario into the St. Lawrence, are now carried across the watershed into the Illinois River, and through that to the Mississippi and the Gulf of Mexico. The canal thus serves as a system of drainage for the City of Chicago, carrying the sewage of that city southward to the Mississippi, and thus protects the water supply of that city, which is taken from Lake Michigan.

Permission to divert water from Lake Michigan was first granted by my predecessor, Secretary Alger, on May 8, 1899. He permitted a flowage of 5,000 cubic feet per second, but his permit contained the following conditions:

1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

2. That if, at any time, it becomes apparent that the current created by such drainage works in the south and main branches of Chicago River be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as

may be demanded by navigation and property interests along said Chicago River and its south branch.

Subsequently, during the administration of Secretary Root, the amount of the current permitted to be taken was modified or restricted until December 5, 1901, when it was fixed at the amount now permitted, and these permits contained the condition—

that the permission herein given shall be subject to such modifications as in the opinon of the Secretary of War the public interests may from time to time require.

On March 14, 1907, an application made for permission to divert an additional 4,000 cubic feet per second for the purpose of reversing the current of the Calumet River and flowing that river also through the canal to drain the southern portion of Chicago was denied by Secretary Taft in an opinion in which he referred once more to the desirability of submitting 'this question of capital and national importance to the Congress of the United States.'

It is clear that even under the conditions heretofore manifested on these applications, the proposition to divert the waters of Lake Michigan into another watershed has not been entertained without hesitation and careful restriction by my predecessors. The propriety of obtaining congressional sanction for the project has been pointed out from the beginning; and the form in which the permit has been granted, even for the moderate amount of diversion permitted, has been so phrased as to indicate that the permission was predicated upon the absence of any substantial injury to commerce.

The sanitary canal has never received the direct sanction of Congress. It was build solely under the authority of the State of Illinois, as given in its 1889 general act for creating sanitary districts. And although pursuant to the suggestion of my predecessors the question of the propriety of its diversion of water from Lake Michigan was presented urgently in the reports of the Chief of Engineers for the years 1899 and 1900 as transmitted to Congress, no action upon the question has ever been taken by that body. In the argument before me it was urged that the present canal represented the growth and development of a national policy expressed in two acts of Congress, 1822 and 1827, which authorized the construction of a canal 'to connect the Illinois River with Lake Michigan,' thus connecting the two watersheds. (Acts of March 30, 1822, and March 2, 1827.) But these statutes

authorized a canal for the purpose of navigation and not sanitation. (*Missouri* v. *Illinois*, 200 U. S. 526.) The Illinois and Michigan Canal, actually constructed under their authority, derived its water for navigation purposes from the Calumet, Des Plaines, and Chicago Rivers, and not from the Lakes. And although in the latter part of its existence it was used to a very slight extent to help purify the waters of the Chicago River and thus sanitate the City of Chicago, such a purpose could not have been dreamed of at the time its construction was authorized by Congress, 90 years ago. I can not see that its authorization and construction offer the slightest congressional sanction for the great canal now under discussion, which was not even contemplated until much more than half a century later. Even at the time when the present canal was constructed and opened it is very evident that its ultimate possible effect upon the navigation of the Great Lakes was not clearly realized by those interested in that navigation. The evidence before me indicates that the withdrawal of water from Lake Michigan at Chicago would require about five years to produce its full effect upon the levels of the Great Lakes (see report of International Waterways Commission on Chicago Drainage Canal, p. 7) and that this effect would be still further observed by periodic oscillations in the lake levels. These facts may easily explain any inaction on the part of the Nation and their representatives to this withdrawal of water and make it clear that any argument of implied acquiescence must be scrutinized with unusual care.

In this respect the situation is now very different. The present application was opposed by representatives of 23 cities and 6 States interested in harbors and commerce upon the Great Lakes, notably the Cities of Duluth, Milwaukee, Toledo, Cleveland and Buffalo. It was opposed by representatives of the navigation interests engaged on the Chicago River as well as on the Great Lakes, and by the official representatives of the Canadian Government as well as private Canadian interests engaged in the navigation of the Lakes and the St. Lawrence River, including representatives of the Cities of Kingston and Montreal.

A very careful consideration of the voluminous evidence and statements submitted, as well as a consideration of the reports of other commissons and boards of engineers who have investigated the subject, leaves no doubt in my mind that the withdrawal of 10,000 cubic feet

per second would substantially interfere with the navigable capacity of the Great Lakes and their connecting rivers. The Chief of Engineers, whose statutory authority in passing upon this application is concurrent with and independent of my own, and whose opinion upon such a question of scientific conclusion must be given especial weight, so states in his recommendation. His conclusions are corroborated by the authority of other boards of investigation, notably the report of the International Waterways Commission of January 4, 1907.

Careful observations and calculations conducted under the offices of the United States Lake Survey and reported through the Chief of Engineers, covering observations for the last 46 years, indicate that a withdrawal of 10,000 cubic feet per second would reduce levels at various places as follows:

	Inches
Lakes Huron and Michigan	6.9
Lake St. Clair	6.3
Lake Erie	5.4
Lake Ontario	4.5
St. Lawrence River at Rapide Plat	4.8 plus

The foregoing effects would be produced at mean lake levels; the lowering effects would be much greater at low-water periods—the precise time when any additional shortage would be most keenly felt. This reduction would create substantial injury in all of the American harbors of the Great Lakes and in the St. Marys', St. Clair and Detroit Rivers. It would produce equal injury in Canadian harbors on the Great Lakes, and a still greater injury on the lower St. Lawrence, the Canadian officials claiming a probable lowering effect of 12 inches at Montreal at low water.

The United States has improved about 106 harbors and rivers on the Great Lakes affected by this diversion and has spent on such improvements over ninety millions of dollars. The Canadian Government has improved over 50 harbors on Georgian Bay and Lakes Huron, St. Clair, Erie and Ontario. By treaty, American vessels are accorded equal rights of navivation with Canadian vessels in all these waters, including the St. Lawrence River. The reduction of the water in these harbors and channels would diminish to just that extent the amount of these improvements, and would nullify to just that extent the effects of the moneys which have been appropriated for that purpose by the respective Governments. Connecting

various portions of these waterways are the two canals at the Sault Ste. Marie, the Welland Canal, and a number of canals on the St. Lawrence River. The available depth of water over one or all sills of each of these canals would be affected, and in some cases reconstruction might even be made necessary.

The enormous lake traffic which uses these harbors and these rivers is increasing with great rapidity, both in gross volume and in the size and average drafts of the vessels employed therein. The Chief of Engineers reports that to lower the water surface 6 inches would reduce the permissible load of one of the large modern vessels by from 300 to 550 tons, with a consequent loss of from $3,600 to $7,500 in freights for such vessel per season. The International Waterways Commission reported that it would be a conservative estimate which would make the loss to the navigation interests resulting from a reduction of 6 inches in the depth of water as $1,500,000 per annum, or a sum which, capitalized at 4 per cent., would amount to a loss of $37,500,000 (see third progress report of International Waterways Commission of Dec. 1, 1907, p. 24). The lowest careful estimate of injury to American vessels alone is reported by the Chief of Engineers at $1,000,000 per year.

The argument was made before me that, owing to the well-known fact that the levels of the lake vary, owing to winds and change of barometic pressure, by amounts even greater than the reduction which would be caused by this canal, therefore the proposed reduction is of no consequence. This argument is well disposed of in the report of the International Waterways Commission of January 4, 1907, on page 8, as follows:

It is evident that the average level of the lake may be lowered considerably without the change becoming immediately apparent, and that fact has been used as an argument to prove that the lowering caused by the Chicago Drainage Canal is of no consequence to those interested in navigation. Since they cannot see it they will not know it and will not feel it. The argument is fallacious. It is true that they cannot see it immediately, but they will soon feel it and will know it through the most costly means of acquiring knowledge—the injury to their material interests. The oscillations will remain the same as before, but low water will fall lower and high water will rise less high. The average draft of vessels must be diminished by the amount that the average

level is lowered unless the depth be restored by remedial works.

In a word, every drop of water taken out of Chicago necessarily tends to nullify costly improvements made under direct authority of Congress throughout the Great Lakes, and a withdrawal of the amount now applied for would nullify such expenditures to the amount of many millions of dollars, as well as inflict an even greater loss upon the navigation interests using such waters.

On the other hand, the demand for the diversion of this water at Chicago is based solely upon the needs of that city for sanitation. There is involved in this case no issue of conflicting claims of navigation. The Chief of Engineers reports that so far as the interests of navigation alone are concerned, even if we should eventually construct a deep waterway from the Great Lakes to the Mississippi over the route of the sanitary canal, the maximum amount of water to be diverted from Lake Michigan need actually be not over 1,000 feet per second, or less than a quarter of the amount already being used for sanitary purposes in the canal. This estimate is confirmed by the report of the special board of engineers on the deep waterway from Lockport, Ill., to the mouth of the Illinois River, dated January 23, 1911. It is also confirmed by the practical experience of the great Manchester Ship Canal in England. From the standpoint of navigation alone in such a waterway too great a diversion of water would be a distinct injury rather than a benefit. It would increase velocity of the current and increase the danger of overflow and damage to adjacent lands.

We have, therefore, presented in this case claims of entirely different characters and jurisdictions — the claim of sanitation on the one side and of navigation on the other; the vital interest of a single community on the one side and the broad interest of the commerce of the nation on the other. The discretion given to the Secretary of War under sections 9 and 10 of the act of 1899 is very broad, but I have very grave doubts as to whether it was intended to authorize him to grant a permit which would inflict a substantial injury upon commerce in order to benefit sanitation. The entire purpose and scope of that legislation was to make him the guardian of commercial interests of the nation represented in their waterways. And while he sometimes under that statute must decide that the interests of one class of transportation

are less important and must yield to the conflicting interests of another class. I have considerable doubt whether it was intended to give him authority to sacrifice substantial interests of navigation to entirely different claims over which he normally has no jurisdiction whatever.

But however that may be, and without resting my decision upon the question of my legal authority, I am quite clear as a matter of discretion that under the facts presented by this case no further diversion of water should be permitted at Chicago without the direct sanction of the Congress of the United States. I do not for one moment minimize the importance of preserving the health of the great City of Chicago; but when a method of doing this is proposed which will materially injure a most important class of the commerce of the nation and which will also seriously affect the interests of a foreign power, it should not be done without the deliberate consideration and authority of the representatives of the entire nation. The growth of Chicago is phenomenal and its representatives are quite unwilling to put any final limit to the demand which may be made upon the waters of Lake Michigan for its sanitation under the system now in use. I have before me the report of 1911 of the president of the sanitary district in which he says:

I am of the opinion that the presumption that our water supply is to be limited to 10,000 cubic feet per second, or 600,000 cubic feet per minute, is gratuitous and mischievous and should not be voiced by the officials of this district. I believe that we should have the volume requisite to our needs as they appear and are justified.

It is therefore quite conceivable that compliance with their sanitary needs according to this method of sanitation may eventually materially change this great natural watercourse now existing through the Lakes. The weighing of the sanitation and possibly the health of one locality over against the commerce of the rest of the Nation and the consideration of our relations and obligations to Canada in respect to a great international waterway are not matters of mere technical or scientific deduction. They are broad questions of national policy. They are quite different in character, for example, from the question of fixing the proper location of a pierhead line or the height or width of a drawbridge over a navigable stream—fair samples of the class of questions which come to the Secretary of War for decision under

the above-mentioned act of 1899. While the researches and opinions of experts in the respective fields are necessary and useful as an assistance toward reaching a fair and proper policy, the final determination of that policy should belong not to an administrative officer but rather to those bodies to whom we are accustomed to entrust the making of our laws and treaties.

In my view of the proper exercise of my discretion in this matter the foregoing considerations are sufficient for a decision of this case. Having reached the conclusion that the proposed diversion of the waters of Lake Michigan would substantially injure the interests of the navigation on the Great Lakes which it is my legal duty to protect, it would clearly follow that the present application should be denied.

I have carefully examined, however, the evidence which both sides have introduced bearing upon the sanitary needs of the City of Chicago, and my conclusion is in no way shaken. I am not persuaded that the amount of water applied for is necessary to a proper sanitation of the City of Chicago. The evidence indicates that at bottom the issue comes down to the question of cost. Other adequate systems of sewage disposal are possible and are in use throughout the world. The problem that confronts Chicago is not different in kind but simply larger and more pressing than that which confronts all of the other cities on the Great Lakes, in which nearly 3,000,000 people of this country are living. The urban population of those cities, like that of Chicago, is rapidly increasing, and a method of disposition of their sewage which will not injure the potable character of the water of the Lakes must sooner or later be found for them all. The evidence before me satisfies me that it would be possible in one of several ways to at least so purify the sewage of Chicago as to require very much less water for its dilution than is now required by it in its unpurified condition. A recent report of the engineers of the sanitary commission (Oct. 12, 1911) proposes eventually to use some such method, but proposes to postpone its installation for a number of years to come, relying upon the present more wasteful method in the meanwhile. It is manifest that so long as the city is permitted to increase the amount of water which it may take from the Lakes, there will be a very strong temptation placed upon it to postpone a more scientific and possibly more expensive method of disposing of its sewage. This is particularly true in

view of the fact that by so doing it may still further diminish its expenses by utilizing the water diverted from the Lakes for water power at Lockport. But it must be remembered that for every unit of horsepower realized by this water at Lockport four units of similar horsepower would be produced at Niagara, where the natural conditions are so much more favorable. Without, therefore, going more into detail in a discussion of this question, I feel clear that no such case of necessity has been presented by the evidence before me as would justify the proposed injury to the many varied interests in the great waterways of our lakes and their appurtenant rivers.

It remains only to consider certain special arguments that have been pressed upon me: It has been urged that the levels of the lakes, even if lowered, could be restored by compensating works. To a certain extent that is true. But the very nature of this consideration offers another illustration of the importance of having the whole question passed upon by Congress. Such compensating works can only be constructed by the authority of Congress and at very considerable cost. It is not a matter which is in the hands of the Secretary of War. Permission to divert water which will at one and the same time nullify the effect of past appropriations and make necessary similar expenditures in the future, should be granted only with the express consent of the body in whose hands the making of such appropriations and the authorization of such works rest.

Furthermore, in most cases such compensating works could only be constructed with the joint consent of our neighbor Canada. The United States Government alone would be unable, even if it were willing to spend its own funds, to compensate for the damage done through the lowering of these levels unless Canada were willing to join in constructing the portion of such works which would necessarily stand upon Canadian soil.

The question therefore becomes not merely national but international, and this leads me to the consideration of the arguments which were urged by both sides in reference to the treaty with Great Britain in respect to Canada of January 11, 1909. A careful consideration of that treaty fails to indicate to me that it is in any way controlling upon the questions now before me. It gives to the citizens of both countries certain mutual rights of navigation in the waters of the Great Lakes and their connect-

ing rivers; but beyond that the question of the right to this diversion at Chicago seems to me to have carefully excluded. The applicants for the permit have urged upon me that article 8 of the treaty gives a preference to the uses of water of the lakes for domestic and sanitary purposes over the uses of such water for navigation. Article 8, however, applies only to future cases brought before the International Joint Commission; and furthermore I am clearly of the opinion that the domestic and sanitary purposes referred to in that article were intended to be the "ordinary" uses of such waters for domestic and sanitary purposes referred to in article 3. It would be quite contrary to our own national policy to give such a preference to an extraordinary sanitary use of such a character as to create a substantial injury to navigation. The matter has been before our own Supreme Court in the case of the Unites States v. the Rio Grande Dam & Irrigation Co. (174 U. S., 690). In that case the Supreme Court held that a company which proposed to take the water of the Rio Grande river for the purpose, among others, "of supplying water to cities and towns for domestic and municipal purposes" could be prevented from so doing when the result would be a substantial injury to the navigability of the Rio Grande river farther down. In its opinion the court said:

The question always is one of fact, whether such appropriation substantially interferes with the navigable capacity within the limits where navigation is a recognized fact. In the course of the argument, this suggestion was made, and it seems to us not unworthy of note, as illustrating this thought. The Hudson river runs within the limits of the State of New York. It is a navigable stream and a part of the navigable waters of the United States, so far at least as from Albany southward. One of the streams which flows into it and contributes to the volume of its waters is the Croton river, a non-navigable stream. Its waters are taken by the State of New York for domestic uses in the City of New York. Unquestionably the State of New York has a right to appropriate its waters, and the United States may not question such appropriation, unless thereby the navigability of the Hudson be disturbed. On the other hand, if the State of New York should, even at a place above the limits of navigability, by appropriation for any domestic purposes, diminish the volume of waters, which, flowing into the Hudson, make it a navigable stream, to such an extent as to destroy its navigability,

undoubtedly the jurisdiction of the National Government would arise and its power to restrain such appropriation be unquestioned; and within the purview of this section (act of Sept. 19, 1890, ch. 907) it would become the right of the Attorney General to institute proceedings to restrain such appropriation.

The treaty, however, contains provisions in its article 10 by which "any questions or matters of difference arising between the high contracting parties involving the rights, obligations, or interests of the United States or of the Dominion of Canada, either in relation to each other or to their respective inhabitants, may be referred for decision" to an international joint commission established by the said treaty. The hearing before me brought forth the fact that the Government of Canada regards the proposal contained in this application as one which affects the material interests of that country. The establishment by formal treaty between the two countries of a tribunal with jurisdiction to decide just such questions seems to me to afford an additional reason against the assumption of jurisdiction to decide the question by an administrative officer of one of those countries.

In short, after a careful consideration of all the facts presented, I have reached the following conclusions:

First. That the diversion of 10,000 cubic feet per second from Lake Michigan, as applied for in this petition, would substantially interefere with the navigable capacity of the navigable waters in the Great Lakes and their connecting rivers.

Second. That that being so, it would not be appropriate for me, without express congressional sanction, to permit such a diversion, however clearly demanded by the local interests of the sanitation of Chicago.

Third. That on the facts here presented no such case of local permanent necessity is made evident.

Fourth. That the provisions of the Canadian treaty for a settlement by joint commission of "questions or matters of difference" between the United States and Canada offer a further reason why no administrative officer should authorize a further diversion of water, manifestly so injurious to Canada, against Canadian protest.

The prayer of the petition is therefore denied.

Henry L. Stimson, Secretary of War."

Answer of the Sanitary District of Chicago to complaint in the Main Channel suit—filed January 16, 1914, as follows (Vol. VIII, pp. 58-126, including exhibits):

(1) Admits it is municipal corporation, organized under the laws of Illinois, as charged in the bill of complaint; a copy of the original act under which the defendant was organized, passed May 29, 1889, is attached as Exhibit A.

(2) Admits the Chicago River is situated in Cook County, and originally flowed in a general easterly direction and is formed as described. Exhibit B, attached, shows the location of the river exactly.

(3) Admits the Chicago River and its branches are navigable waters of the United States.

(4) Admits the United States has expended the amount of money alleged in the bill of complaint, in improving the navigable capacity of said river and the harbor at its mouth.

Avers that $2,389,527.10 of said amount was expended in the improvement of the harbor at the mouth of said Chicago River; that down to the year 1896, the complainant had expended no money in the improvement of the Chicago River itself. That the balance of that original sum, namely, the sum of $1,626,539.20, was expended by complainant in and about the improvement of the Chicago River between the year 1896 and June 30, 1913; that the City of Chicago, beginning with the year 1861 and ending the first day of January, 1913, has expended in the improvement of the Chicago River, $6,272,574.52; that the defendant, the Sanitary District, has expended in the improvement of the Chicago River, in addition to the amounts expended by the City of Chicago, the sum of $10,640,739.52; that defendant made said expenditures for the purpose of enabling it to cause the flow of the several amounts of water provided for under the laws of Illinois, and the expenditures by the defendant did improve the capacity and navigability of said Chicago River and its several branches.

(5) Admits the passage of the Rivers and Harbors Act of March 3, 1899, and the continuance in force of Section 10 thereof.

(6) Denies that application was made by defendant for permission to divert any certain quantity of water from Lake Michigan through said Chicago River and its main channel. Avers that application was made to the Secretary of War for permission to open the channel constructed and cause the water of the Chicago River to flow into same, pursuant to and under the Act of May 29, 1889; that in the said permit the Secretary of War stated that he reserved the right to close said discharge or to modify it to such an extent as might be demanded by navigation and property interests along said Chicago River and its south branch.

(7) Admits the order of Secretary of War of April 9, 1901, concerning the limitation of flow to 200,000 cubic feet per minute.

(8) Admits the issuance of the order of July 23, 1901.

(9) Admits the issuance of the order of December 5, 1901.

(10) Admits the issuance of the order of the Secretary of War of January 17, 1903.

(11) Admits the application to the Secretary of War of November 28, 1906, for permission to construct a canal connecting the Calumet River with the main channel of defendant, and the refusal of the Secretary of War of March 14, 1907, to grant said permit. A copy of the statement of the Secretary of War is attached as Exhibit C.

(12) Admits the permit of September 11, 1907, to construct a canal connecting Lake Michigan at Wilmette, to the north branch of the Chicago River, a copy of which is attached as Exhibit D.

(13) Admits the issuance of the permit of June 30, 1910, with reference to the construction of the Calumet Sag Channel, a copy of which is attached as Exhibit E.

(14) Admits the making of the application of February 5, 1912, to divert 10,000 cubic feet of water per second through the Chicago and Calumet Rivers.

(15) Admits the refusal of the Secretary of War of January 8, 1913, to grant said application of February 5, 1912.

(16) Denies that defendant has, for a long period of time, diverted and abstracted from Lake Michigan, and is at present diverting 400,000 to 600,000 cubic feet of water per minute, as charged in the bill of complaint.

(17) Denies the diversion of water from Lake Michigan in excess of the amount of 250,000 cubic feet of water per minute has lowered or will lower the levels of Lakes Michigan, Huron, St. Clair, Erie, Ontario, the Rivers Sault Ste. Marie, St. Mary's, St. Clair, Detroit, Niagara and St. Lawrence, or any of them, or any of the harbors, channels, canals or rivers connected therewith, or will injure or diminish or create an obstruction to the navigable capacity of said rivers, as charged.

(18) Neither denies nor affirms the allegation as to the amount of the expenditure by the United States in improving said harbors and channels. Denies that the diversion of waters from Lake Michgan in excess of the permits, has or will have a tendency to undo or annul the orders of Congress, as charged.

(19) Denies that the diversion from Lake Michigan in excess, or substantially in excess, of the amount provided by the permits of the Secretary of War, will modify the condition and capacity of the channel of the Chicago River, as charged.

(20) Denies that the diversion from Lake Michigan in excess of permits, will alter or modify the condition and capacity of Lakes Michigan, Huron, St. Clair, Erie, Ontario, the Rivers Sault Ste. Marie, St. Mary's, St. Clair, Detroit, Niagara and St. Lawrence, or any of them, and the ports, roadsteads, havens, harbors, canals and harbors of refuge

connected with the above named waters, or any of them. Denies that defendant cannot lawfully continue to divert and abstract waters from Lake Michigan as it now does, or that it cannot lawfully divert and abstract, without the permission of the Secretary of War, waters from Lake Michigan under the laws of Illinois, and by and through the channels and works it has already constructed; that complainant will be in any manner injured by the diversion through its works; that interstate navigation and commerce will in any manner be injured by the abstraction, pursuant to and under the laws of Illinois, and as contemplated by the channels and works of the defendant.

The remainder of the answer consists of affirmative allegations as follows:

(21) The Sanitary District is a municipal subdivision of the State. The area within its territorial limits is 386.2 square miles, located on the shore of Lake Michigan at its southwest end. The shore line is thirty-three miles long and the Sanitary District limits extend westward from the shore line a distance from six to fourteen miles. The drainage naturally is to Lake Michigan, for the most part through the Chicago and Calumet Rivers and their branches. The DesPlaines River rising in Wisconsin twelve miles from the Lake Michigan shore flows in a southerly direction at a distance of about ten miles from the lake paralleling it until the DesPlaines reaches a point fifteen miles southwest of the mouth of the Chicago River when it turns to the southwest a distance forty-five miles beyond, and empties into the Illinois River. Between Lake Michigan and the DesPlaines River, six miles from the shore line is an elevation of approximately eleven feet above the low water level of the lake. This is known as the Continental Divide, or the height of land on one side of which water flows into the Great Lakes thence into the Gulf of St. Lawrence, and on the other side of which water flows into the DesPlaines River, thence into the Illinois and Mississippi Rivers, then to the Gulf of Mex-

ico. By water trail from the mouth of the Chicago River, the lowest point in said Continental Divide is about eight miles. At this point there was located on the summit of said Divide a lake known as Portage Lake and later called Mud Lake. At times of high water, the DesPlaines River rose to the level of said lake and discharged itself over the divide and through the Chicago River into Lake Michigan. The land lying east of said divide is low, flat, level and swampy, and devoid of hills or elevations so that in times of high water large portions of said territory were inundated. The City of Chicago was established at the mouth of the Chicago River, located approximately in the center of the territorial limits of this defendant and, as it has expanded, has stretched out over the branches of the Chicago River. From the time when the site where the City of Chicago is now located, was settled, it has been menaced by floods and has had to contend with the natural disadvantages which it suffered by reason of the fact that the city was situated upon a flat, low, sandy soil and at the outlet or discharging point of a large drainage area. Prior to the organization of Chicago, from the time this part of the territory of North America was discovered, a trading post was located at the mouth of the Chicago River. In 1778 there was a fort, known as Fort Dearborn, which was destroyed in the massacre of 1812. Fort Dearborn was rebuilt by the United States in 1816. In 1837, the village of Chicago was organized with 709 lawful voters. By 1854, there were 40,000 people in Chicago. From the very beginning, because of the flat, low, marshy and sandy soil, and only a slight elevation above the level of Lake Michigan, the city was confronted with the necessity of constructing a sewer system. It raised the level of its streets. Between 1854 and 1889, sewers were so constructed that in the City of Chicago, north of the Chicago River, they drained into the Chicago River as far north as the boundaries of the City of Chicago. Territory lying to the west of the north and south branches of the Chicago river was drained by sewers into the river. Territory lying south of the Chicago

River and east of State street, drained directly into Lake Michigan, that is, sewers were constructed at 12th street, 22d street and 31st street, which emptied directly into the lake. The territory above described as being within the boundaries of the City of Chicago as it existed in 1889 was bounded on the north by Fullerton avenue, at a distance of two and one-half miles north of the Chicago River, on the west by Western avenue at a distance of between four and five miles west of Lake Michigan, and on the south by 39th street, a distance of approximately four and one-half miles south of the mouth of the Chicago River.

(22) South of 39th street and adjoining the City of Chicago was the Village of Hyde Park, with a population in 1889 of 41,000, the largest part of which had sewers emptying directly into Lake Michigan. West of Hyde Park was the Town of Lake, with a population of 58,661 in 1889, the sewage of which emptied into the South Fork of the South Branch of the Chicago River. Situated north of Fullerton avenue and adjoining the City of Chicago was the Town of Lake View with a population of 42,339, which had several sewers emptying into the North Branch of the Chicago River. And situated west of the Town of Lake View was the Town of Jefferson, with a population of 10,662, the sewers of which emptied into the North Branch of the Chicago River. The population of Chicago in 1889 was 802,651. The discharge of the sewage of Chicago and its adjoining suburbs either into Lake Michigan directly or indirectly by way of the Chicago River and its branches polluted the water supply of this great population. Conditions of pollution were such that it became necessary to create The Sanitary District of Chicago for the purpose of removing said pollution and providing the way, as hereinafter more fully shown, of disposing of the sewage of the City of Chicago and its adjacent towns and villages.

(23) When Chicago was first organized, the people of the village obtained their drinking water from shallow wells sunk into the sand, the water in said wells finding its way

by seepage from Lake Michigan and the Chicago River. As Chicago grew, the wells became polluted by sewage and by drainage that washed into said wells necessitating large numbers of people obtaining their water supply directly from Lake Michigan. This water was first obtained by means of wagons carting the water from the lake to individual users. Later wooden pipes were laid in the streets, which drew water from the lake. Still later, a tunnel was extended to Lake Michigan and the Chicago avenue crib was built to prevent the ends of the tunnels being injured or choked by ice in the winter time. Finally, the City of Chicago, or the towns and villages located near it and herein mentioned, built in Lake Michigan six intakes, cribs and tunnels connected therewith for the purpose of obtaining water from Lake Michigan, as follows:

The Lake View crib on the northern extremity of said city, at a distance of two miles from the shore of Lake Michigan; the Carter H. Harrison crib, situated at a distance of three miles from the shore; the Chicago avenue crib, situated at a distance of two miles from the shore; the Four Mile crib, situated approximately four miles from the shore and opposite the most densely populated portion of said City of Chicago, and the Hyde Park and Edward F. Dunne cribs, two miles off shore, situated near the southern extremity of said city. At points along the shore, pumping stations were erected by means of which water is pumped through said tunnels and distributed through pipes or water mains to the people of Chicago and adjoining towns. The distributing system is interconnected so that in case any one crib or tunnel should be incapacitated, the other tunnels would furnish water to the people. The City of Chicago has expended, in and about the construction of said cribs and tunnels, and in the construction of distributing pipes and distributing tunnels, large sums of money, in excess of $59,042,565. There is no other source of water supply for the inhabitants of Chicago and its adjoining towns than Lake Michigan.

(24) From the earliest discovery of this country, there has existed between Lake Michigan and the Mississippi River a water route used as a highway of trade and travel. This water route originally consisted of the Chicago River, its South Branch and the West Fork thereof, a ditch or canal in wet seasons and a portage in dry seasons from thence into a lake known as Mud Lake, and a ditch or canal in wet seasons and a portage in dry seasons from said Mud Lake into the DesPlaines River to the Illinois River and thence into the Mississippi River. The said route was used for the purpose of carrying on trade and for the purpose of travel for upwards of 160 years, and said use was prior to any improvements made by the United States or by the government then controlling the country now known as Canada. During said period, also, from the lower end of Lake Michigan through the Great Lakes and their connecting waters to the Atlantic Ocean, there were two water routes, one by way of a portage around Niagara Falls and from thence on the St. Lawrence River to the Atlantic Ocean; the other water route consisted of a route through Georgian Bay, Lake Nipissing and down the Ottawa River into the St. Lawrence River and thence to the Atlantic Ocean. The two water routes from the lower end of Lake Michigan to the Atlantic Ocean and the one to the Gulf of Mexico were used for the purpose of trade and travel up to approximately the year 1830. About the year 1822, there was a great demand for the improvement of these water routes and on March 30, 1822, the Congress of the United States passed an Act granting to the State certain public lands for the purpose of aiding the State in constructing a canal "connecting the Illinois River with the southern end of Lake Michigan." Said Act was entitled "An Act to Authorize the State of Illinois to Open a Canal Through the Public Lands to Connect the Illinois River with Lake Michigan." Section 1, among other things provided:

> "That the State of Illinois be, and is hereby authorized to survey and mark, through the public lands of the United States, the route of the canal connecting the Illinois River with the southern bend of Lake Michigan; and

ninety feet of land on each side of said canal shall be forever reserved from any sale to be made by the United States, except in the cases hereinafter provided for, and the use thereof forever shall be, and the same is hereby vested in the said State for a canal, and for no other purpose whatever; on condition, however, that if the said State does not survey and direct by law said canal to be opened, and return a complete map thereof to the treasury department, within three years from and after the passage of this act; * * * and grant hereby made shall be void and of none effect;"

The State of Illinois did not, within the time provided by the Act, cause a survey to be made and the grant in said Act lapsed. On January 28, 1826, the General Assembly of Illinois memorialized Congress setting forth the advantages of a canal to unite the waters of Lake Michigan with the Illinois River. The action of the government of Great Britain in refusing to the citizens of the United States free navigation of the St. Lawrence River also made it necessary for the United States to provide a free and unobstructed water route from the Great Lakes to the Atlantic Ocean by way of the Des Plaines River, Illinois and Mississippi Rivers, and the Gulf of Mexico. Thereupon, on March 2, 1827, the Congress of the United States passed an Act entitled "An Act to grant a quantity of land to the State of Illinois for the purpose of aiding in opening a canal to connect the waters of the Illinois River with those of Lake Michigan." Section 1 of said Act is, in part, as follows:

"* * * That there be and hereby is granted to the State of Illinois, for the purpose of aiding the said State in opening a canal to unite the waters of the Illinois River with those of Lake Michigan, a quantity of land equal to one-half of five sections in width, on each side of said canal, and reserving each alternate section to the United States, to be selected by the Commissioner of the Land Office, under the direction of the President of the United States, from one end of the said canal to the other; Provided, That the said canal when completed, shall be and forever remain a public highway for the use of the Government of the United States, free from any toll, or

other charge, whatever, for any property of the United States, or persons in their service passing through the same;"

On January 9, 1836, the General Assembly of Illinois passed an Act under which the said Illinois-Michigan canal was built to unite the waters of the Illinois River with those of Lake Michigan, entitled, "An Act for the Construction of the Illinois and Michigan Canal," Section 16 of which Act is as follows:

> "That said canal shall not be less than forty-five feet wide at the surface, thirty feet at the base, and of sufficient depth to insure navigation, to be supplied with water from Lake Michigan and such other sources as the Canal Commissioner may think proper, and to be constructed in the manner best calculated to promote the permanent interests of the country, reserving ninety feet on each side of said canal to enlarge its capacity whenever in the opinion of the Board of Canal Commissioners the public good shall require it."

The plan of said canal as contemplated under the said Act of January 9, 1836, provided for a flow of water from Lake Michigan by gravity into and through the canal and from thence into the Illinois River and was known as the "Deep-Cut" plan. On account of lack of funds, the State was unable to immediately construct the said canal on the deep cut plan and it was constructed on what was known as the shallow cut plan and completed in the year 1848. Water to partly operate the same was obtained from Lake Michigan by means of pumps. From the time the canal was opened until the construction of the main channel of the Sanitary District, it furnished a partial outlet for the sewage and drainage of Chicago. As the needs of the city required, said canal was enlarged so as to provide a better and more suitable outlet. About the year 1860, to meet the demands of increased population, larger pumps were installed to pump more water from Lake Michigan through the Chicago River into the Illinois and Michigan Canal. In the year 1865, to meet the further needs of Chicago, the General Assembly of Illinois passed an

Act entitled "An Act to Provide for the Completion of the Illinois and Michigan Canal upon the plan adopted by the State in 1836," which said Act is in part as follows:

> "Whereas, it has been represented that the City of Chicago, in order to purify or cleanse Chicago River, by drawing sufficient quantity of water from Lake Michigan, directly through it, and through the summit division of the Illinois and Michigan Canal, would advance a sufficient amount of funds to accomplish this desirable object; and,
>
> Whereas, the original plan of said canal was to cut down the summit so as to draw a supply of water for navigation directly from Lake Michigan, which plan was abandoned for the time being, after a large part of the work had been executed, only in consequence of the inability of the State to procure funds for its further prosecution; • • •
> now therefore, • • •
>
> Be it enacted by the People of the State of Illinois, represented in the General Assembly: That to secure the completion of the Illinois and Michigan Canal upon the original "deep cut" plan, with such modifications and changes of line, if necessary, as will most effectually secure the thorough cleansing or purification of the Chicago River, and facilitate the execution of the work, the City of Chicago, through its constituted authorities, may at once enter into an arrangenment with the board of trustees of said canal, with a view to the speedy accomplishment of the work."

The work of completing the said canal by the City of Chicago was completed about the year 1871. Thereafter, water of Lake Michigan was drawn through said canal by gravity and about the year 1884, pumps were installed at Bridgeport, the northern terminus of the canal, whereby a larger quantity of water was withdrawn from Lake Michigan through the Chicago River and said canal, all pursuant to a resolution of the General Assembly of Illinois passed in the year 1881, which resolution is in part as follows:

> "Whereas, The State of Illinois, in General Assembly, did, on the sixteenth day of February, 1865, grant and authorize the City of Chicago in the State of Illinois, to

deepen the Illinois and Michigan canal for the purpose of, and with the intent to better the system of sewage of the said City of Chicago by permitting a free flow of water from Lake Michigan through the Chicago River and said canal to the Desplaines and Illinois Rivers; and the City of Chicago did perfect said improvement in conformity with said permission; * * *

Whereas, the deepening of the canal as aforesaid has proved to be totally inadequate for the purposes intended, and the large amount of sewage of the City of Chicago, being far greater than the capacity of the canal and the water now passing through it to deodorize and render innocuous; and

Whereas, The foulness of the water annually causes the death of millions of fish in the Desplaines and Illinois Rivers, that float to the shores and decay; * * *

Whereas, The supplying of the canal from these sources will so dilute and weaken the sewage of the City of Chicago, as to greatly relieve it of its foulness and stench to the great delight, relief and health of the peoples near to and bordering upon the line of the canal, the Desplaines and Illinois Rivers; therefore be it Resolved"

The resolution then provided that the City of Chicago should cause pumps to be installed at the northern terminus of the canal whereby at least 60,000 cubic feet of water per minute should be pumped from the Chicago River into the canal.

(25) Lake Michigan was, is and will be the only adequate source from which drinking water for the metropolitan population of Chicago and its environs could or may be obtained, and the supply is adequate, sufficient and pure if unpolluted by sewage or drainage. The additional flow of water to the Illinois and Michigan Canal created by the pumping works installed in 1884 at Bridgeport did not serve to cleanse sufficiently the Chicago River of pollution. During a portion of each year, the Chicago River did flow into the lake thus carrying with its waters the sewage and drainage of Chicago and its environs, polluting the water of Lake Michigan. The population had increased so that the improvements made from time to time up to the year 1884 were insufficient and

inadequate to prevent the pollution of the lake, thus depriving the inhabitants of Chicago and its environs of a pure water supply for domestic purposes. Thus it became necessary that some further and better improvements be made by which the pollution of the drinking water of the inhabitants of Chicago would be prevented. The death rate from typhoid fever and other water-borne diseases had become very high and deaths from such causes were frequent through the City of Chicago and adjacent towns. The Chicago River and its branches were then a seething mass of septic sludge giving forth noxious and disagreeable odors which caused annoyance and danger to the people of Chicago and persons sojourning within its limits. Thereupon, the City of Chicago appointed a commission consisting of eminent sanitary experts for the purpose of making an investigation of the conditions, and a report as to the proper solution of the problem then confronting the people of Chicago and its environs who depended upon Lake Michigan for their water supply. The commission was appointed in the year 1886 and presented a report to the Mayor of the city recommending the construction of a channel and works connected therewith, substanially as provided for in the Act of May 29, 1889, under which The Sanitary District was organized. The said Act was passed, pursuant to the investigation and report of said commission and other investigations carried on at the same time by other persons. Said Act was passed for the purpose of providing for the organization of The Sanitary District of Chicago and the construction of channels and works by it, so that the pollution of the drinking water of Chicago and its environs would be relieved and a pure supply could be secured.

(26) By the Act of May 29, 1889, the Sanitary District was authorized to construct a channel of sufficient size to take care of not only the sewage and drainage of the City of Chicago and its environs, but also the sewage and drainage as the increase of population might require. The channel to be constructed was fixed by said Act with a capacity and size to produce a flow through the rock sections thereof,

not less than 600,000 cubic feet of water per minute and to produce and maintain a continuous flow of not less than 20,000 cubic feet of water per minute for each 100,000 of population in the Sanitary District. The Chicago River drainage area is approximately 420 square miles, the maximum run of which is approximately 10,000 cubic feet of water per second or 600,000 cubic feet per minute. In order to prevent the Chicago River from flowing into the lake and carrying the sewage into Lake Michigan, it was necessary that the channel so to be constructed should have a capacity of not less than 10,000 cubic feet of water per second, the maximum run-off of the Chicago River drainage area. In order to prevent the pollution of the waters of Lake Michigan by water of the Calumet River, it was necessary that a channel be constructed connecting the Calumet River with the main channel so that the Calumet River would be reversed. It was further provided by said Act under which the Sanitary District was organized that the channel when completed should be a navigable water of the United States and that the United States should have the authority to take over and operate said channel for navigation purposes, but not for sanitary or drainage purposes. The said channel to be constructed was intended to be an enlargement or replacement of the channel known as the Illinois and Michigan Canal.

(27) Pursuant to said Act of the General Assembly of May 29, 1889, the Sanitary District was organized by vote of the people on the 5th day of November, 1889, and the first trustees were elected December 12, 1889. On January 18, 1890, this board of trustees held a regularly organized meeting of the board to begin the actual work of constructing the Sanitary District channel provided for under said Act. The Sanitary District entered upon the construction of said main channel and other works long prior to September 19, 1890, and laid out plans for and entered upon the construction of its channel with a capacity of 840,000 cubic feet per minute or 14,000 cubic feet per second. Plans were at the same time made and considered for the construction of a channel to

connect the Calumet River with the said main channel; for the construction of intercepting sewers on the south side of the city converging at 39th street on the Lake Shore by which approximately 2,000 cubic feet of water per second should be pumped from Lake Michigan together with sewage accumulated at said point, through a conduit to be constructed into the South Fork of the South Branch of the Chicago River, and from thence into the said main channel. Said intercepting sewers so provided for on the south side of the city and converging at 39th street, were for the purpose of intercepting sewage then flowing directly into Lake Michigan, and thereby divert it into the main channel. The North Branch of the Chicago River was then a stagnant stream into which sewage from a large portion of the north side emptied. In order to create a current into said North Branch and thereby cleanse it and abate a public nuisance, plans were made for the construction of a conduit extending from the Lake Shore at Lawrance avenue in the City of Chicago to the said North Branch through which approximately 666 cubic feet of water per second from Lake Michigan should be caused to flow, and from thence into the main channel. It was contemplated that approximately 1,000 cubic feet per second of water from Lake Michigan should be caused to flow through said North Shore channel, together with said sewage and drainage from said district. Plans were then made for enlarging the cross section of the Chicago River, South Branch and West Fork to accommodate sufficient water so as to cause the course, current and flow of the Chicago River to be at all times reversed, in times of high water as well as in times of low water, and to provide for an ultimate flow through the Sanitary District main channel of sufficient water to dilute and purify the sewage of the City of Chicago and its environs flowing into the main channel, pursuant to the provisions of said Act of 1889. At that time the defendant, Sanitary District, entered upon the construction of said works. The complainant, the United States, had knowledge of said act and the improvements provided for under said Act.

(28) Pursuant to said Act of 1889, and said plans, the Sanitary District constructed a channel through what is known as the rock section of the route described, extending from the controlling works at Lockport north to Willow Springs, a distance of 14.93 miles, with a bottom width of 160 feet, a surface width of 162 feet, with a depth of at least twenty-four feet, and with a declivity of one foot in every 20,000 feet, having a capacity of flowing 840,000 cubic feet per minute or 14,000 cubic feet per second. From said Willow Springs to Robey street, a distance of 13.1 miles through what is known as the earth section, the defendant made plans for a channel with a bottom width of 202 feet and a surface width of 300 feet and a depth of not less than twenty-four feet, with a declivity of one foot in every 40,000 feet, Said defendant constructed said channel through said earth section as planned, except in this, that for a distance of 7.8 miles from Robey street to Summit the defendant left unexcavated a width of ninety two feet, inasmuch as said channel was not territory having a rocky stratum and was more easily capable of progressive development as the population of the District might increase. The capacity of said channel from Robey street to Summit, being a portion of the earth section was eighty percent of the flow of the rock sections, or 500,000 cubic feet of water per minute, or 8,000 cubic feet of water per second. Long prior to the filing of the bill of complaint, this defendant made and entered into a contract with the Great Lakes Dredge & Dock Company, under which the said main channel in the earth sections was to be enlarged by widening the same, so that through the said earth section, the said main channel would have a capacity of flowing in excess of 10,000 cubic feet of water per second. Before the filing of the said bill of complaint, the work provided for under said contract was substantially completed, so that the said main channel through the earth sections at the time of the filing of said bill of complaint herein, had a capacity of flowing in excess of 10,000 cubic feet of water per second.

(29) The said main channel from Robey street to the controlling works at Lockport, Illinois, was completed and ready for use on or about September 21, 1898, and about January 11, 1899, pursuant to said Act of 1889, section 27 thereof, such fact was reported to the Governor of Illinois. Whereupon, the governor appointed a commission to inspect and certify the completion of the channel as required by said Act. Pursuant to the report of said commission given the Governor of Illinois, he authorized and directed the opening of said channel.

(30) On January 17, 1900, said channel was opened and the flow of the Chicago River, South Branch and West Fork, as far as Robey street was reversed and water was caused to flow out of Lake Michigan, through the Chicago River, the South Branch and West Fork thereof, and down the Sanitary District channel from Robey street and discharged into the DesPlaines River at Lockport and from thence into the Illinois River to the Mississippi River, and continuing to the Gulf of Mexico.

(31) Contemporaneously with the construction of the main channel, defendant carried on certain construction work in the Chicago River, the South Branch thereof and its West Fork, to provide a larger cross section to enable the Chicago River and the South Branch and the West Fork to flow an increased quantity of water. July 3, 1896, the Sanitary District having made application, obtained a permit from the Secretary of War to enlarge the cross section of the Chicago River and its branches, copies of the application and the permit being attached as Exhibits H and I, respectively. July 11, 1900, the Secretary of War granted two permits to the defendant to make further changes, alterations and improvements in the South Branch of the Chicago River. The application for said two permits, the plans accompanying the same and the permits are attached and marked respectively, J, J-1, K-1, K-2, L and L-1. Pursuant to said permits of July 3, 1896, and July 11, 1900 and other permits granted by the Secretary of War at various times, defendant improved the

Chicago River, South Branch and West Fork so that the rivers have been enlarged sufficiently to accommodate a flow of water of at least 8,000 feet per second with a velocity not to exceed one and one quarter miles per hour. The volume of water above specified flowing through the said rivers and through the main channel of the Sanitary District, together with the 2,000 cubic feet emptying into the South Fork of the said Chicago River from the 39th Street Pumping Station will not create a current in any way injurious to navigation.

In the improvement of said Chicago River and its branches and the widening and deepening thereof and in the building of bridges, the Sanitary District has expended in excess of $10,000,000. A large part of said money was expended for the purpose of improving navigation in the said Chicago River, South Branch and West Fork. The Chicago River was thus deepened by the defendant to a depth of twenty-six feet from a depth of seventeen feet and widened to a width of 200 feet from a width of approximately one hundred feet.

The main channel or canal constructed by this defendant from Robey street to Lockport is twenty-four feet deep at all points and has a width of 162 feet. The Chicago River, South Branch and West Fork as improved by the Sanitary District and the main channel constructed by it are of sufficient capacity to enable the largest vessels, freight or passenger, traversing the Great Lakes, to pass through or into same. By virtue of the works of the defendant, the largest vessel traversing the Great Lakes can pass through said Chicago River and its branches to the city of Joilet. Since the completion of the Sanitary District main channel, the Illinois and Michigan Canal has been abandoned. The improvement of the Chicago River and its branches was in accordance with the plan of the complainant in connection with the improvement of navigation upon the said rivers.

(32) May 14, 1903, the General Assembly of Illinois passed an Act entitled "An Act in Relation to the Sanitary District

of Chicago to enlarge the corporate limits of said District and to construct dams, water wheels and other works necessary to develop and render available power arising from the water passing through its channels, and levying taxes therefor". Under this Act, the defendant extended its main channel to the City of Joilet and the work was completed about the year 1907. Certain works were also constructed and completed about the year 1907 for the development of water power at a cost of approximately $5,000,000. The amount of power being so developed is 30,000 H. P. and is worth approximately $30 per horse power per year net. The revenue obtained from said water power is used for the purpose of partially defraying the other expenses of the defendant. The operation of said hydro-electric plant and the development and sale of electrical energy does not in any way increase the amount of water caused to flow through said main channel and is incidental merely to the operation of the Sanitary District's diversion works. About the year 1910, the Sanitary District built what is known as the North Shore channel extending from Lake Michigan and Wilmette to the North Branch of the Chicago River, with a capacity of 1,000 cubic feet of water per second, which flows from Lake Michigan into and through said North Shore channel to the North Branch of the Chicago River.

(34) Under said Act of 1889, the defendant has constructed intercepting sewers and pumping stations at Lawrence avenue in the City of Chicago, and the Lake, and at 39th street, Chicago, and the Lake, by which all the sewage formerly flowing directly into Lake Michigan is diverted into the main channel aforesaid of this defendant.

In the year 1910, the defendant entered upon the construction of an adjunct or addition to its main channel at Sag, Illinois, known as the Calumet-Sag Channel, to a point on the main channel at Sag, Illinois, which channel is in course of construction, with a capacity of approximately 2,000 cubic feet of water per second. It is capable of enlargement so that it will accommodate a flow of 4,000 cubic feet of water

57

per second. The Calumet Sag Channel is to drain what is called the Calumet District lying immediately south of the southern limits of Chicago and thus prevent the pollution of the drinking water supply by and through the Calumet River. The Calumet Sag Channel is also designed to furnish a certain amount of water by which to dilute sewage and drainage flowing through the main channel of the Sanitary District, and arizing in that portion of the Sanitary District tributary to the Chicago River and its branches and the main channel of this defendant.

(35) The works constructed or being constructed and the improvement made upon the Chicago River and its branches were made necessary by the Act of the General Assembly of Illinois of 1889 and Acts amendatory and supplementary thereto. They provide a complete and comprehensive system by which an outlet is provided for the territory comprised within the limits of the Sanitary District and for the drainage arising therein. Said works do and will prevent the pollution of the drinking water of the inhabitants and provide pure water for drinking and domestic purposes. Said Act of 1889 and acts amendatory and supplemental thereto were passed and adopted under the police power existing in the State for the purpose of protecting the health and lives of the people within said district and within the State of Illinois as well as persons sojourning or visiting within the limits of this defendant. Said works constructed and to be constructed provide the only method by which the sewage and drainage of the inhabitants of the Sanitary District could be diverted from Lake Michigan and a pure water supply for domestic purposes secured for such inhabitants. By virtue of the nearness of the Mississippi drainage area, and the insignificance of the so-called continental divide, it was possible to provide in the manner above set forth, an outlet for the sewage and drainage of the City of Chicago and its environs so that the water of Lake Michigan could be maintained pure and undefiled by any pollution from sewage or drainage arising within the City of Chicago, and other

cities and villages located upon the shore of Lake Michigan near the said City of Chicago. The Sanitary District and the City of Chicago have expended in and about the construction of the works and in making the improvements, the sum of $82,000,000. Of this said amount, the City of Chicago has expended approximately $6,500,000, in and about building intercepting sewers, pumping stations, etc.

(36) The said works constructed and the improvements made and the works being constructed are necessary to preserve the health and lives of the people within the Sanitary District. The Sanitary District comprises a large metropolitan district within Cook County. Attached is a map marked Exhibit M showing the territorial boundaries of the defendant within which there is located numerous cities.

(37) Congress has at various times appropriated money for improvement of navigation in the Illinois River, and for the making of surveys and investigations to determine the best method by which navigation on the Illinois and Des Plaines Rivers could be improved in connection with the main channel of the defendant heretofore constructed. The United States built in the lower Illinois River, certain dams at La Grange and Kampsville for the purpose of improving navigation in connection with and for the purpose of supplementing improvements made by the State of Illinois in constructing two dams, one at Henry, Illinois, and the other opposite Copperas Creek on said river. The dams constructed by the State and the United States were provided with locks by which vessels could pass from the level of the water created by the dam at the lock to the level below, or vice versa. During the period when the said main channel of defendant was under construction, prior thereto and since the opening of same, Congress has appropriated moneys for the purpose of making surveys and investigations for a deep waterway, extending from the terminus of the main channel of the defendant, at or near Lockport, Illinois, on the Des Plaines and Illinois Rivers to the Mississippi River and from thence to the Gulf of Mexico. All boards of engineers and

all engineer officers of the Corps of Engineers of the United States Army, who have made reports in regard to such deep waterway pursuant to congressional appropriations have recommended the improvement of the Des Plaines and Illinois Rivers to provide deep water navigation, and the plans and recommendations made by such engineers, contemplated the use of the said main channel of defendant as part of and as a link in such deep waterway, and the use of the water flowing through and contemplated to be passed through the main channel of the defendant in the Des Plaines and Illinois Rivers for the purpose of such navigation. The International Waterways Commission created by act of Congress and by an act of the Dominion of Canada by report made January 4, 1907, recommended that 10,000 cubic feet of water per second should be allowed to be diverted by the defendant from Lake Michigan. The Sanitary District constructed its main channel with a capacity of not less than 10,000 cubic feet of water per second, to comply with the plans and purposes of the United States. The United States approved said plans and purposes and the Congress of the United States cooperated with the defendant and invited the defendant to cooperate with the complainant, and joined in the improvement of the Chicago River, as has been more fully set out. The Attorney General of the United States, on December 14, 1909, caused a bill of complaint to be filed in the name of the United States against the Economy Light & Power Company, in the Circuit Court of the United States, Eastern Division, Northern District of Illinois, to enjoin the defendant, the Economy Light & Power Company, from constructing a dam in the Des Plaines River. In and by said bill of complaint, complainant further recognized the diversion and the right of defendant to divert the amount of water contemplated in and by its said works and in and by said act of May 29, 1889. Said bill of complaint in this respect, so far as it relates to said matters, is as follows:

"That in connection with the construction of said Sanitary District Canal, and in creating the system of waterways re-

sulting from the construction of said canal, said State of Illinois has caused the quantity of water flowing through said Des Plaines River below the point at which it connects with said canal to be largely increased, and that said portion of said river has been continuously since the opening of said canal, and is now, water navigable in fact and a part of the navigable waters of the United States and subject to the jurisdiction and control of the Federal Government. * * *

That in connection with and as a result of the construction of said Sanitary District Canal and the diversion of said water from Lake Michigan, said Sanitary District of Chicago, acting under authority of said State of Illinois, has largely increased the navigability of said Des Plaines River and that continuously since the opening of said canal there has been, and is, in said portion of said Des Plaines River below the point at which it connects with said canal, a body of water navigable in fact and which, by virtue of its connection with other navigable waters is to be deemed a part of the navigable waters of the United States and subject to the jurisdiction and control of said United States."

Complainant, in and by its bill of complaint in said cause, wherein the Economy Light & Power Company was defendant, based its right to an injunction enjoining the construction of the said dam upon the fact that the State of Illinois had, in and by and pursuant to the Act of May 29, 1889, created a navigable waterway in the DesPlaines River; that said navigable waterway thus created was connected with and was a part of the system of navigable waterways created by the Sanitary District of Chicago, which said waterways thus created were connected with and a part of other navigable waters of the United States.

(38) Complainant had knowledge of the passage of the Act of May 29, 1889, plans of the Sanitary District for the construction of the main channel, and the progress of construction. About the time of the opening of the Sanitary District's main channel the lake survey of the United States

under the direction of the corps of engineers of the United States Army, had determined the increments of the St. Clair, Niagara and St. Lawrence Rivers for the purpose of making estimates or calculations of the effect of the diversion of 10,000 cubic feet per second at Chicago. Said officers of the United States at said time, upon the determination of said increment, calculated the effect of said diversion to be about six inches upon the levels of the Great Lakes below Lake Superior. The United States about the same time, in providing for the improvement of the St. Mary's, St. Clair and Detroit Rivers and other channels connecting the Great Lakes with one another, fixed the reference plane for said improvements six inches lower because of the supposed effect of the said diversion upon the levels of the different lakes. The United States acquiesced in and agreed to said diversion.

If the diversion of water from Lake Michigan to the amount proposed by the Sanitary District, will have the effect of lowering the levels of the waters of the Great Lakes, except Superior, and their connecting channels, it is feasible and practicable to compensate or off set for such lowering by constructing works in the St. Clair, Detroit, Niagara and St. Lawrence Rivers, or in some or all of them. The International Waterways Commission, in its report on the regulation of Lake Erie, issued in the year 1910, recommended the building of regulating works to regulate the levels of Lake Erie and thereby raise such levels approximately one foot at low water times, the cost of which works was estimated by said commission at approximately $796,000. A more recent report of said commission on the regulation of said Lake Erie, estimates the cost of such works at approximately $3,000,000. Such regulating works would more than off-set for any alleged lowering of the levels of the Great Lakes and their connecting channels due to the Chicago diversion.

The levels of the waters of said Great Lakes and their connecting channels, have been lowered by works constructed

by the United States and by Canada, by private individuals and corporations, by and with the consent and acquiescence of the United States. The defendant is not responsible for any lowering of said levels.

(39) By consenting to the improvement of the Chicago River to accommodate the flow of water through the Sanitary District's main channel, as contemplated under the Act of 1889, by the appropriation of money for the purpose of determining the feasibility of improving waterways to connect with the navigable waterways created by this defendant, by acquiescing in and acknowledging the right to use said works and to abstract the water from Lake Michigan as proposed, solemnly asserted in the case of *United States* v. *The Economy Light & Power Company,* above referred to, by allowing this defendant to proceed with the construction of said works, with the knowledge of said complainant, without making any objection thereto, but, on the contrary, consenting to and agreeing to various improvements made necessary by virtue of the said system of works, complainant has estopped itself from making any objection to or attempting to prevent further use and continuance of said works for the purpose for which they were created. After the beginning of the construction of said works of the Sanitary District, the United States adopted the improvements contemplated and being then carried on in the Chicago River and its various branches and supplementing said improvements so being made by the defendant and inviting further improvements, itself expended approximately $1,000,000 in the improvement of the Chicago River from Rush street to the end of the West Fork.

(40) Defendant has never recognized the right of the United States in any manner to interfere with the construction, operation or use of its main channel, adjuncts or additions, or the right of the United States to determine or direct how the said main channel and its appurtenances should be operated or used, or the amount of water that should be abstracted from Lake Michigan through its various adjuncts

or channels, to carry out the purposes of said Act of May 29, 1889. Application for permits mentioned and described in the bill of complaint and in this answer, were made by reason of the close blending or association of the two governments, namely the Government of the State and of the United States. The defendant desired, if possible, to obtain the consent of the Secretary of War for the construction, operation and use of its works, but defendant never has admitted and does not admit, but on the contrary denies the right of the United States to determine the amount of water that should be caused to flow through said main channel or its adjuncts. The permit of May 8, 1899, granted to the Sanitary District the right to open the main channel and use the same for the purposes and to cause the amounts of water to flow therein as contemplated and provided for under the Act of May 29, 1889. The only condition of said permit as to limiting the amount of water to be allowed to flow through the said main channel, is the preservation of suitable conditions of navigation upon the Chicago River itself. Said condition was inserted in said permit by virtue of the fact that at that time the Chicago River had not been widened and deepened to the extent that it was proposed to be. The orders subsequently given by the Secretary of War to reduce the flow or to increase the flow of water through the Chicago River, were based entirely upon conditions of the Chicago River for the purpose of navigation. By said permit of May 8, 1899, and the subsequent orders and permits issued by the Secretary of War, the United States recognized the right of the Sanitary District to abstract water from Lake Michigan, and only limited the amount of such abstraction by the amount that the Chicago River could carry without injury to navigation thereon. Subsequently to the issuance of said permits and orders, the project for the widening and deepening of the Chicago River for a capacity of at least 8,000 cubic feet of water per second, was carried out with the consent of the Secretary of War. Before the filing of the bill of complaint herein, defendant had improved the Chicago River channel so that at least 8,000 cubic feet of water per

second could flow and was flowing into and through the said Chicago River and the South Branch and West Fork thereof, without creating a current of more than one and one quarter miles per hour and without creating a condition which would be or was injurious to navigation on said river. The condition created by the defendant in improving the Chicago River by widening and deepening it, greatly improved navigation in all respects upon said river.

(41) The water discharged into the DesPlaines River from the Sanitary District's works, flows through said Des Plaines River and empties into the Illinois River. As a result of this flow, the Illinois River has become navigable without the use of government or state dams heretofore constructed, so that the Illinois River may now be traversed by boats of a deeper draft than could have traversed the Illinois River by the use of the locks and dams constructed by the United States and by the State, namely, the Kampsville and LaGrange dams by the United States and the Henry and Copperas Creek dams by the State of Illinois. The Illinois River has become clear, which prior to the opening of the defendant's main channel was a sluggish, slow moving body of water badly polluted by sewage discharged by the City of Chicago and many towns and villages situated along it. Fish life in said river has increased rapidly and generally it has become more healthful to the people living thereon. If the flow of the Illinois River had not been increased by the waters caused to flow therein by defendant, or if the flow through the main channel of the defendant, were limited to 4,167 seconds feet, as charged that it should be, or to any amount materially less than required by said Act of May 29, 1889, it would be necessary for the cities and towns located on said Illinois and DesPlaines Rivers to expend vast sums of money in treating the sewage now discharged in the said Illinois River, in order to prevent a public nuisance.

(42) Since the opening of the defendant's main channel and the completion of the additions and adjuncts thereto, in-

cluding intercepting sewers, the health conditions in the City of Chicago and in other towns and villages located within the defendant's territorial limits have greatly improved and the death rate from water-borne diseases has greatly diminished. A pure water supply has been provided for said people. The City of Chicago is a great railroad and commercial center, and is a primal market. Many persons not residing within the limits of the Sanitary District, come each year from all parts of the United States and the world to Chicago, and remain there for various periods. Twenty-seven million people each year come into and leave the City of Chicago. In addition, there are forty-seven million persons residing without the City of Chicago, but in the suburban communities, who enter and leave Chicago each year.

(43) If the injunction prayed for is granted and defendant is obliged to limit the withdrawal of water to 4,167 seconds feet, a large portion of the moneys expended will have been lost, and the works constructed will be practically useless and of no substantial efficiency or value. The City of Chicago and other cities and towns and villages within the boundaries of the defendant, have constructed their waterways, water mains and other sewage disposal works and water supply works, upon the basis of the works of this defendant being permanant, to endure for all time, to be operated as provided by the Act of May 29, 1889, and acts amendatory and supplementary thereto. If the said flow of water through said main channel is reduced or limited to 4,167 cubic seconds feet, in order to prevent said sewage from becoming a public nuisance, it will be necessary to construct a plant or plants for the disposal of sewage by some other method or means. The construction of such plants would cost upwards of a hundred million dollars, and the annual operation of such system would cost over seven million dollars, which capitalized at five per cent, would mean a total investment or burden of two hundred and forty million. It will be necessary to construct, in connection with said disposal works, filtration works to filter all the drinking

water and water used for domestic purposes, at a cost of upwards of twenty-five million dollars, and an annual operation cost of two million dollars, making the total investment or burden, forty million dollars. The damage to the City of Chicago and other cities, towns and villages located within the boundaries of the Sanitary District, thus would amount to approximately three hundred million dollars, and the money expended for defendant's works already constructed at a cost of approximateyl eighty-two million dollars, would have been expended for no practical purpose, so far as taking care of sanitary conditions is concerned. The only method by which defendant can conveniently take care of and remove the sewage and drainage from its limits and protect the water supply of the inhabitants of Chicago and its environs, is the one laid out under the Act of May 29, 1889, and acts amendatory and supplementary thereto. The method or methods which it would be necessary for defendant to adopt if the flow of water through its main channel were limited to 4,167 seconds feet, would not accomplish the purpose now secured by defendant's works already constructed, nor would such works constructed under a plan made necessary by such limitation of flow, in any manner equal the efficiency of defendant's works.

(44) The State of Illinois under said Act of May 29, 1889, and acts amendatory and supplementary thereto, provided a comprehensive and effective method to dispose of the sewage within the boundaries of the defendant, and to provide pure drinking water for the inhabitants thereof and its floating population—to wit, the method of treating the sewage by dilution and diverting the same from Lake Michigan. Defendant is without power to provide any other method than the one set forth under the Act of May 29, 1889. If it were given power to dispose of the sewage by some other method and procure a pure water drinking supply in some other manner the constitutional limitation of the State of Illinois upon the creation of indebtedness by municipalities would prevent this defendant from providing the moneys

with which to build sewage disposal works and filtering plants to meet the conditions which would be created by said decrease of the flow of water. Defendant could not provide sufficient funds to build said works. Neither the City of Chicago nor the other cities, villages or towns within the limits of the Sanitary District, have the power to raise sufficient moneys by the sale of bonds or by taxation, to build sewage disposal works or water purification or filtration works which would be necessary to be constructed within the limits of the respective cities, towns and villages, if this defendant were compelled to limit the flow of water to 4,167 feet.

(45) If said injunction is granted and defendant is restrained as requested, it will be unable to keep the drainage water which will flow from said territory from reversing the Chicago River at various times during each year, so that the said drainage and sewage arising tributary to the Chicago River, will flow into Lake Michigan and thereby pollute the water supply of Chicago and other cities and towns within the Sanitary District's limits. At other times during the year, the river will become polluted, so that there would be thereby created an offensive condition and a public nuisance in the spread of water borne diseases, endangering the health and lives of the population of defendant and its floating population.

(46) The sewage disposal works and water filtration plants necessary to be constructed if such injunction were granted, would be, inadequate, ineffective and impracticable to provide for the disposition of the sewage aforesaid, and to provide pure drinking water for the inhabitants of said District. The purification of sewage artificially and the filtration of water polluted by sewage or an effluent arising from sewage purification work is a method for providing a water supply used only where the method provided for under the Act of 1889, to wit, the dilution method and diverting sewage and drainage from the water supply, is impossible.

Exhibit A to answer.—"An act to create sanitary districts and to remove obstructions in the DesPlaines and Illinois Rivers". Approved May 29, 1889, by the General Assembly of Illinois; in force July 1, 1889. (Vol. VIII; Rec. 92-107.)

Section 1. This section generally provides for the organization of the Sanitary District by vote of the people on petition of certain number of legal voters, which petition shall also describe the territorial limits of the Sanitary District.

Sections 2, 3, 4, 5 and 6 set forth how the trustees shall be elected, the number, salaries, proof of ordinances, orders and resolutions, and publication of appropriations.

Section 7 is as follows:

> "7. The board of trustees of any sanitary district organized under this act shall have power to provide for the drainage of such district by laying out, establishing, constructing and maintaining one or more main channels, drains, ditches, and outlets for carrying off and disposing of the drainage (including the sewage) of such district, together with such adjuncts and additions thereto as may be necessary or proper to cause such channels or outlets to accomplish the end for which they are designed in a satisfactory manner; also to make and establish docks adjacent to any navigable channel made under the provisions hereof for drainage purposes, and to lease, manage and control such docks, and also to control and dispose of any water power which may be incidentally created in the construction and use of said channels or outlets, but in no case shall said board have any power to control water after it passes beyond its channel, waterways, races or structures into a river or natural waterway or channel, or water-power or docks situated on such river or natural waterway or channel: Provided, however, nothing in this act shall be construed to abridge or prevent the State from hereafter requiring a portion of the funds derived from such water-power, dockage or wharfage to be paid into the State Treasury to be used for State purposes. Such channels or outlets may extend outside of the territory included within such sanitary district and the rights and powers of said board of trustees over the portion of such channel or outlet lying outside of such district shall be the same as those

vested in said board over that portion of such channels or outlets within the said district.

Sections 8, 9, 10 and 11 provide that the District may purchase real estate, borrow money, raise money by taxation, and let contracts for work in certain manner.

Section 12 is in part as follows:

"Provided, that no part of the taxes hereby authorized shall be used by such drainage district for the construction of permanent fixed, immovable bridges across any channel constructed under the provisions of this act; And provided further, that all bridges built across such channel shall not necessarily interfere with or obstruct the navigation of such channel, when the same becomes a navigable stream, as provided in section 24 of this act, but such bridges shall be so constructed that they can be raised, swung, or moved out of the way of vessels, tugs, boats, or other water craft navigating such channel; And provided further that nothing in this act shall be so construed as to compel said district to maintain or operate said bridges, as movable bridges, for a period of nine years from and after the time when the water has been turned into said channel pursuant to law, unless the needs of general navigation on the DesPlaines and Illinois rivers, when connected by said channel, sooner require it."

Sections 13, 14, 15 and 16 provide for special assessments, issuance of bonds and condemnation of property.

Section 17 is as follows:

"17. When it shall be necessary in making any improvements which any district is authorized by this act to make, to enter upon any public property or property held for public use, such district shall have the power so to do and may acquire the necessary right of way over such property held for public use in the same manner as is above provided for acquiring private property, and may enter upon, use, widen, deepen and improve any navigable or other waters, waterways, canal or lake: Provided, the public use thereof shall not be unnecessarily interrupted or interfered with, and that the same shall be restored to its former usefulness as soon as practicable: Provided, however, that no such district

shall occupy any portion of the Illinois and Michigan canal outside of the limits of the county in which such district is situated for the site of any such improvement, except to cross the same, and then only in such a way as not to impair the usefulness of said canal, or to the injury of the right of the State therein, and only under the direction and supervision of the canal commissioners: And, provided further, that no district shall be required to make any compensation for the use of so much of said canal as lies within the limits of the county in which said district is situated except for transportation purposes."

Sections 18, 19 and 19*a* provide certain limitations as to special assessments, and that the Sanitary District shall pay damages resulting to lands by the operation of its works including attorneys' fees of plaintiff to be assessed as part of the costs of suit.

Sections 20, 21, 22, 23, 24, 25 and 26, are as follows:

"20. Any channel or outlet constructed under the provisions of this act which shall cause the discharge of sewage into or through any river or stream beyond or without the limits of the district constructing the same shall be of sufficient size and capacity to produce a continuous flow of water of at least two hundred cubic feet per minute for each one thousand of the population of the district drained thereby, and the same shall be kept and maintained of such size and in such condition that the water thereof shall be neither offensive or injurious to the health of any of the people of this State; and before any sewage shall be discharged into such channel or outlet, all garbage, dead animals and parts thereof, and other solids shall be taken therefrom, and said district shall, at the time any sewage is turned into or through any such channel or channels, turn into said channel or channels not less than twenty thousand cubic feet of water per minute for every one hundred [fol. 181] thousand inhabitants of said district, and shall thereafter maintain the flow of such quantity of water.

"21. In case any sanitary district in this State formed under the provisions of this act shall introduce sewage into any river or stream of water, or natural or artificial water course, beyond or without the limits of such district, without conforming to the provisions of

this act, or having introduced such sewage into such water course, shall fail to comply with any of the provisions of this act, an action to enforce compliance shall be brought by the Attorney General of this State in the courts of any county wherein such water course is situated, or he may authorize the State's Attorney of any such county to commence and prosecute such action in any such county: Provided, that nothing in this section contained shall be construed to prevent the prosecution of any action or proceedings by individuals or bodies corporate or politic against such district: And, provided further, that if any individual or the authorities of any municipal corporation shall file with the Attorney General a verified statement, in writing, setting forth wherein said sanitary district has failed to comply with any of the provisions of this act, it shall be the duty of the Attorney General forthwith to file in the Supreme Court of this State a petition for mandamus, setting forth wherein said sanitary district has failed to comply with the provisions of this act, and said court shall thereupon hear and determine such cause and proceed to enforce compliance with the provisions of this act, as in other cases of mandamus.

And, in order to comply with the provisions of this act, such sanitary district is hereby authorized and empowered to levy and collect such tax, as an emergency tax, upon the taxable property of such sanitary district as may be necessary to carry into effect any order, judgment or decree of said court relating to the requisite flowage of water, capacity of the channel or outlet and the construction, maintenance and operation of movable bridges, as required by this act.

22. Nothing in this act contained shall be so construed as to constitute a contract or grant between the State of Illinois and any sanitary district formed under its provisions, or to prevent, debar or deprive the State of Illinois from, at any time in the future, altering, amending or repealing this act, or imposing any conditions, restrictions or requirements other, different or additional to any herein contained upon any sanitary district which may be formed hereunder.

23. If any channel is constructed under the provisions hereof by means of which any of the waters of Lake Michigan shall be caused to pass into the Des Plaines or Illinois river such channel shall be constructed of sufficient size and capacity to produce and maintain

at all times a continuous flow of not less than 300,000 cubic feet of water per minute, and to be of a depth of not less than fourteen feet, and a current not exceeding three miles per hour, and if any portion of any such channel shall be cut through a territory with a rocky stratum where such rocky stratum is above a grade sufficient to produce a depth of water from Lake Michigan, of not less than eighteen feet, such portion of said channel shall have double the flowing capacity above provided for, and a width of not less than one hundred and sixty feet at the bottom capable of producing a depth of not less than eighteen feet of water. If the population of the district draining into such channel shall at any time exceed 1,500,000 such channel shall be made and kept of such size and in such condition that it will produce and maintain at all times a continuous flow of not less than 20,000 cubic feet of water per minute for each 100,000 of the population of such district, at a current of not more than three miles per hour, and if at any time the general government shall improve the Des Plaines or Illinois rivers, so that the same shall be capable of receiving a flow of 600,000 cubic feet of water per minute, or more, from said channel, and shall provide for the payment of all damages which any extra flow above 300,000 cubic feet of water per minute from such channel may cause to private property so as to save harmless the said district from all liability therefrom, then such sanitary district shall within one year thereafter, enlarge the entire channel leading into said Des Plaines or Illinois rivers from said district to a sufficient size and capacity to produce and maintain a continuous flow throughout the same of not less than 600,000 cubic feet of water per minute with a current of not more than three miles per hour, and such channel shall be constructed upon such grade as to be capable of producing a depth of water not less than eighteen feet throughout said channel, and shall have a width of not less than one hundred and sixty feet at the bottom. In case a channel is constructed to the Desplaines river as contemplated in this section it shall be carried down the slope between Lockport and Joilet to the pool commonly known as the upper basin of sufficient width and depth to carry off the water the channel shall bring down from above. The district constructing a channel to carry water from Lake Michigan of any amount authorized by this act, may correct, modify and remove obstructions in the Desplaines and Illinois rivers wherever it shall be necessary

so to do to prevent overflow or damage along said river, and shall remove the dams at Henry and Copperas Creek in the Illinois river, before any water shall be turned into the said channel. And the canal commissioners, if they shall find at any time that an additional supply of water has been added to either of said rivers, by any drainage district or districts, to maintain a depth of not less than six feet from any dam owned by the State, to and into the first lock of the Illinois and Michigan Canal at La Salle, without the aid of any such dam, at low water, then it shall be the duty of said canal commissioners to cause such dam or dams to be removed. This act shall not be construed to authorize the injury or destruction of existing water power rights.

24. When such channel shall be completed, and the water turned therein, to the amount of three hundred thousand cubic feet of water per minute, the same is hereby declared a navigable stream, and whenever the general government shall improve the Desplaines and Illinois rivers for navigation, to connect with this channel, said general government shall have full control over the same for navigation purposes, but not to interfere with its control for sanitary or drainage purposes.

25. Any district formed hereunder shall have the right to permit territory lying outside its limits and within the same county to drain into and use any channel or drain made by it, upon such payments, terms and conditions as may be mutually agreed upon, and any district formed hereunder is hereby given full power and authority to contract for the right to use any drain or channel which may be made by any other sanitary district, upon such terms as may be mutually agreed upon, and to raise the money called for by any such contract in the same way and to the same extent as such district is authorized to raise money for any other corporate purposes: Provided, that where the united flow of any sanitary districts thus co-operating shall pass into any channel constructed within the limits of the county wherein such districts are located, and which passes into the Desplaines or Illinois rivers, such united flow shall in no case and at no time be less than 20,000 cubic feet of water per minute for each one hundred thousand of the aggregate of the population of the districts co-operating: Provided, nothing in this act shall in any wise be so construed as to diminish, impair or remove any right or rights of any city, village, township or corporation, body politic or individual situated on

the Desplaines or Illinois rivers or their tributaries and within the valleys of the same to use the channel for drainage or otherwise not inconsistent with the rights of the district constructing the same as expressed in this act.

26. Whenever in any such sanitary district there shall be a city, incorported town or village, which owns a system of waterworks and supplies water from a lake or other source which will be saved and preserved from sewage pollution, by the construction of the main channel, drain, ditch or outlet herein provided for, and the turning of the sewage of such city and district therein, and there shall be in such sanitary district any territory bordering on any such city, incorporated town or village within the limits of another city, incorporated town or village, which does not own any system of waterworks, at the time of the creation of such sanitary district, then upon application by the corporate authorities of such latter named city, incorporated town or village the corporate authorities of such city, incorporated town or village having such system of waterworks shall furnish water at the boundary line between such municipalities by means of its waterworks to the corporate authorities asking for the same in such quantities as may be required to supply consumers within said territory, at no greater price or charge than it charges and collects of consumers, within its limits for water furnished through meters in like large quantities.

Section 27 provides for reporting the completion of the channel to the Governor of Illinois, the inspection of the works by a Commission to be appointed by him, and report showing that the Sanitary District had complied with the Act and thereupon the authorization by the Governor for the opening of the channel.

Here follows description of certain acts amendatory and supplementary to the original act. (Vol. VIII, pp. 107-112.)

May 13, 1901, the General Assembly passed an act, approved July 1, 1901, specifically authorizing the building of bridges over navigable streams and acquirement of right of way by condemnation for the purpose of widening and deepening any river or stream required.

May 14, 1903 the General Assembly passed an act in force July 1, 1903, Section 1 of which enlarged the District's territorial limits by adding the territory south of 87th street in the City of Chicago, known as the Calumet District, which is drained by the Calumet Sag Channel and other territory.

Sections 2, 3, 5, 6 and 8 being the pertinent sections of this Act, are as follows:

"2. The board of trustees of said sanitary District shall have the right to provide for the drainage of the additional territory added to said sanitary district by this act by laying out, establishing, constructing and maintaining one or more channels, drains, ditches and outlets for carrying off and deposing of the drainage (including the sewage) of such district, together with such adjuncts and additions thereto as may be necessary or proper to cause such channels or outlets to accomplish the end for which they are designed in a satisfactory manner and shall have the right to use what is known as the "Calumet feeder" of the Illinois and Michigan canal and lands adjacent to such feeder belonging to the State of Illinois for the site of any such channel, within the limits of the county in which such district is situated, in such manner as said district may elect, and shall also have the right to construct a channel across said Illinois and Michigan canal, without being required to restore said Illinois and Michigan canal or said feeder to its former usefulness. If by reason of said abandonment, a stagnant stream or pool of water shall remain upon the deposits of Chicago sewage, accumulated in said Illinois and Michigan Canal by reason of its years of usefulness by the city of Chicago as a sewage outlet, said sanitary district shall fill up said canal to a depth sufficient to remove said condition and prevent the spread of pestilence and disease throughout the territory in which said Illinois and Michigan Canal is abandoned; and the other powers and jurisdiction of said sanitary district of Chicago over and in connection with such added territory shall be the same as that vested in it over the territory included within the limits of said sanitary district as originally organized. Before said Calumet channel is connected with the present main sanitary channel, gates of suitable pattern for shutting off the flow of water into said Calumet channel shall be installed at or near the connection of said Calumet channel with the Calumet river and forever maintained for use in

case of an emergency, and for the protection of the property and lives of residents of the Illinois valley, and shall maintain the same proportion of dilution of sewage through such auxilliary channels as it may construct and join to its main channel as is now required by the act creating said sanitary district: Provided however, that before any such channel is constructed across said Illinois and Michigan Canal, or the navigation of said canal in any manner interfered with, said sanitary district of Chicago shall connect its present main channel from the controlling works at Lockport with the upper basin of the Illinois and Michigan Canal at Joilet by a channel of a depth of not less than ten (10) feet and a width of not less than one hundred and sixty (160) feet through its entire length, in which channel so to be constructed said sanitary district shall provide and construct a lock or locks of the size of at least twenty-two (22) feet in width by one hundred and thirty (130) feet in length between mitre sills, connecting upper and lower levels, and provide suitable protection for water craft in using said locks and channel. Said locks shall be constructed of the most approved pattern of their size, and be perfectly safe for use and be equipped with machinery to operate the same; and if only one lock is constructed it shall be provided with double gates to prevent accident, and said sanitary district shall forever maintain and operate the same. Provided, further, that said sanitary district shall furnish and provide at said lock a site of the dimensions of at least twenty by thirty feet upon which the State through the Canal Commissioners shall have the right to erect a suitable office building and keep an agent therein, and the Canal Commissioners shall have such authority in and about said lock as is necessary to enforce the rules and regulations prescribed by them pertaining to and governing navigation on the Illinois and Michigan Canal: Provided, further: That said sanitary district shall furnish, free of all expense, for the perpetual use of the Canal Commissioners, at some point in the township of Lockport to be agreed upon by the Canal Commissioners and the sanitary district trustees, a strip or parcel of land bordering upon said sanitary channel, eight hundred (800) feet in length and one hundred and thirty (130) feet in width, filling the same to a suitable depth to provide suitable roadways for approaches, whereon may be located, constructed and operated docks, shops, barns and other buildings controlled by the Canal Commissioners and used in connection with the operation of the Illinois and Michigan Canal.

3. Said sanitary district shall permit all water craft navigating or proposing to navigate said Illinois and Michigan Canal to navigate the water of all said channels of said sanitary district promptly, without delay and without payment of any tolls or lockage charges for so navigating in said channels. The rules of the United States government now in force, regulating navigation on the Chicago river shall govern navigation on the channels of said sanitary district of Chicago; Provided however, that the speed of all vessels while passing through the earth sections shall not exceed eight (8) miles per hour.

5. That the said sanitary district of Chicago is hereby authorized to construct all such dams, waterwheels and other works north of the upper basin of the Illinois and Michigan Canal as may be necessary or appropriate to develop and render available the power arising from the water passing through its main channel and any auxiliary channels now or hereafter constructed by said district.

6. That the power made available by the works constructed under the provisions of this act shall be converted into electrical energy and shall be transmitted to the various cities, villages and towns within said sanitary district or adjacent to the main channel of said sanitary district and may be used in the lighting of said cities, villages and towns, or parts thereof, or for the operation of pumping plants or machinery used for municipal purposes or for public service, or may be disposed of to any other person or corporation, upon such terms and conditions as may be agreed to by the said sanitary district; Provided, however, that it shall be the duty of said sanitary district to utilize so much of said power as may be required for that purpose to operate the pumping stations, bridges and other machinery of said sanitary district.

8. The said sanitary district shall at the expense of said district, in all respects comply with the provisions of the acts of Congress of March 22, 1822, and March 2, 1827, as construed by the courts of last resort of the State of Illinois and of the United States, in relation to the Illinois and Michigan Canal, so far as it affects that portion of the Illinois and Michigan Canal vacated or abandoned by the terms of this act.

Exhibit "C" to Answer.

March 14, 1907.

In the Matter of the Application of THE SANITARY DISTRICT OF CHICAGO to Reverse the Flow of the Calumet River

This application is made under Section 10 of the act of March 3, 1899 (30 Stat. L., 1151), which provides as follows:

> "Sec. 10. That the creation of any obstruction, not affirmatively authorized by Congress, to the navigable capacity of any of the waters of the United States is hereby prohibited; and it shall not be lawful to build or commence the building of any wharf, pier, dolphin, boom, weir, breakwater, bulkhead, jetty or other structures in any port, roadstead, haven, harbor, canal, navigable river, or other water of the Unites States, outside established harbor lines, or where no harbor lines have been established, except on plans recommended by the Chief of Engineers and authorized by the Secretary of War; and it shall not be lawful to excavate or fill or in any manner to alter or modify the course, location, condition, or capacity of, any port, roadstead, haven, harbor, canal, lake, harbor of refuge, or inclosure within the limits of any breakwater, or of the channel of any navigable water of the United States, unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same."

The application of the Sanitary District is for leave to reverse the flow in the Calumet River in such a way as to make the water to flow out of the lake instead of to flow into it and to discharge the water from the Calumet River into the Drainage Canal. The Chief of Engineers was at first of opinion that such a change in the flow of the river *it* was not within the power of the Chief of Engineers to recommend, or within the power of the Secretary of War to permit. This expression of opinion as to the construction of the statute was submitted to the Judge Advocate General, who holds that Section 10, as quoted above, applies to this case and and that it is one in which work could be allowed under the recommendation of the Chief of Engineers and the permission of the Secretary of War. Upon the con-

struction of the Judge Advocate General I requested the Chief of Engineers to make his recomendation, which he has done as follows:

February 23, 1907.

1. Respectfully returned to the Secretary of War.

2. The subject of the abstraction of water from Lake Michigan has been elaborately investigated by the Lake Survey Office at Detroit, and the results are published in the annual reports of the Chief of Engineers for the years 1900, 1902 and 1904. The international Waterways Commission has also given it careful consideration, and its conclusions are set forth in report of January 4, 1907, printed as War Department Document No. 293.

3. In my opinion, this abstraction will undoubtedly lower the levels of all the waters of the Great Lakes, except those of Lake Superior, and thus diminish the navigable capacity and depth of the various channels and harbors which have been deepened and improved under authority of Congress.

4. Leaving out Lake Superior, there are more than 100 works of river and harbor improvements on the Great Lakes and their connecting waters, for which appropriations aggregating more than $80,000,000 have been made. The application of this vast sum has resulted in securing and maintaining specified depths and widths of channel, which Congress has decided to be required for the accommodation of the traffic using those waters.

5. To diminish these depths even to a slight extent, would not only prove a serious injury to the traffic, but would practically undo the work which has been accomplished by Congressional direction, and necessitate the expenditure of further large sums of money for restoration. Any project that tends, in a measure, to annul or reverse the orders of Congress, as expressed in the various river and harbor acts appropriating funds for improving the harbors and channels connecting with the Great Lakes, should meet the disfavor of the Department, unless it has been sanctioned by that body. In my judgment, such a project is the one under consideration, and for this reason I am unwilling to recommend favorable action thereon, assuming that the Department is empowered to take such action, as is held by the Judge Advocate General.

A. Mackenzie, *Brig. Gen.*
Chief of Engineers, U. S. Army.

It is quite evident from the reading of the statute that the Congress intended in this statute, as in many others, to give the Chief of Engineers authority, independent of the Secretary of War, in reaching a conclusion as to the wisdom and propriety of granting a permit under the section, and that unless the Chief of Engineers shall recommend the granting of the permit, the Secretary of War is without power to give the requested authority. It follows, therefore, that the appliaction must be denied whatever my view of the case.

The decision of the Chief of Engineers and its final character has made it unnecessary for me to consider the merits of the question, but I may say this much, that the appliaction for a change in the Calumet River is to be made the basis for the withdrawal of a large amount of water from Lake Michigan and that all interested in the enormous lake traffic view the settlement of the question with grave apprehension. Added to this, is the international complication which is likely to arise in the threatened lowering of the lake level in the ports and harbors and canals of Canada. On the other hand, it is maintained with great emphasis and elaboration of detail that the change in the Calumet River, is essential to the healthful sanitation of Chicago, and that the threatened injury to navigation is so small as to be negligible.

Between two such great interests, the decision must be affected more or less by large public policy and expediency, and while I agree in the construction of the Judge Advocate General that the issue is left by statutes to the recommendation of the Chief of Engineers and the concurrent decision of the Secretary of War, it may be fortunate that circumstances now require submission of this question of capital and national importance to the Congress of the United States.

Wm. H. Taft, Secretary of War."

Exhibit "D" to Answer.

Permit.

"War Department,

Washington, September 11, 1907.

Sir: Referring to your letter of 2nd instant, in which you request approval of proposed drainage channel to connect Lake Michigan at Wilmette, Ill., with the North Branch of the Chicago River; also permission to con-

struct a pile crib in Lake Michigan at mouth of same, and to deposit filling within the limits of such crib, I beg to inform you that the War Department will interpose no objection to the project as set forth in your letter and indicated on drawing submitted, provided the following conditions are complied with:

1. That the pier constructions, the filling behind the same, and the excavation of the proposed channel shall be done subject to the supervision and approval of the local officer of the Corps of Engineers, U. S. Army, at Chicago, so far as to see that the work authorized is not exceeded;

2. That the total diversion of water from Lake Michigan through the Chicago River into the Illinois River shall be no greater than already authorized by past War Department permits;

3. That the work shall be commenced before December 31, 1908, and completed within five years thereafter.

Very respectfully, Robert Shaw Oliver, Acting Secretary of War. G. M. Wisner, Esq., Chief Engineer the Sanitary District of Chicago, American Trust Building, Chicago, Illinois."

Exhibit "E" to Answer.

"Permit

War Department,
Washington, June 30, 1910.

Sir: Referring to your application of the 27th instant on behalf of the Board of Trustees of The Sanitary District of Chicago to open a channel from the Calumet River to its existing Main Channel so as to substitute two routes instead of one between Lake Michigan and its canal, I have the honor to advise you to the following effect:

It appears from the records of the Department that by an instrument executed May 8, 1899, The Sanitary District of Chicago was given permission to connect its Drainage Canal with the South Branch of the Chicago River at Robey Street, in the City of Chicago, and to divert the waters of Lake Michigan through the Chicago River into said canal, subject to certain specified conditions designed to limit the amount of such diversion and in other ways to protect the public interest. The per-

mission so granted was subsequently modified at various times, and by an instrument executed December 5, 1901, the amount of flow was fixed at not exceeding 250,000 cubic feet per minute, equivalent to 4,167 cubic feet per second, which is the present rate allowed. At the time the original permit was given a connection with the Calumet River was not mentioned but if it had been it is probable that a connection with that river as well as with the Chicago River would have been allowed.

So long as the water-flow remains unchanged there seems to be no special objections to its extension to both rivers instead of confining it to a single one, especially since if the new (Calumet) route be developed later to a navigable state the double route will be advantageous to navigation interests. Accordingly, in view of the favorable recommendation of the Chief of Engineers and of the consent thereto by the Attorney General, under the conditions hereinafter prescribed, the Department hereby modifies the existing permission so as to allow the division of the already permitted water-flow in such manner as to reach the Sanitary District Canal by way of the Calumet River and a connecting channel, as well as by way of its present route through the Chicago River, subject to all pertinent conditions of the existing permissions and to other express conditions, as follows:

(a) That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of The Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

(b) That if at any time it became apparent that the current created by such drainage work in the Calumet, as well as Chicago rivers, be unreasonably obstructive to navigation, or injurious to property, the Secretary of War reserves the right to close the discharge through said channel or rivers, or to modify it to such an extent as may be demanded by navigation and property interests along said rivers.

(c) That The Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in the Calumet as well as Chicago River.

(d) That the amount of water withdrawn from Lake Michigan through the Chicago and Calumet rivers together, shall not exceed the total amount of 250,000 cubic

feet per minute (4,167 cubic feet per second) already authorized to be withdrawn through the Chicago River alone.

(e) That the permission herein given shall be subject to such modification as in the opinion of the Secretary of War the public interests may from time to time require.

(f) That this permission shall in nowise affect or in any manner be used in the friendly suit now pending in the Circuit Court of the United States for the Northern District of Illinois brought by the United States of America against the Sanitary District of Chicago, to determine the right of the said Sanitary District to divert from Lake Michigan for sanitary purposes an amount of water in excess of that now being diverted, without having first obtained a permit from the Secretary of War.

(g) That the War Department shall have free access at all times to the waterflow records of The Sanitary District of Chicago and free access also to the regulating works and all other parts of its canals for the purpose of checking records or making water-flow measurements.

(h) That the plans for the proposed work shall be submitted to and approved by the Chief of Engineers and the Secretary of War.

(i) That the work shall be subject to the supervision and approval of the Engineers Officer of the United States Army in charge of the locality.

Very respectfully, Robert Shaw Oliver, Acting Secretary of War. Mr. George M. Wisner, Chief Engineer Sanitary District of Chicago, Chicago, Ill."

"Memorial to Congress on the Subject of the Illinois and Michigan Canal

(Laws Extra Session, 1826, p. 97)

To the Honorable the Senate and House of Representatives of the United States of America in Congress assembled:

The memorial of the General Assembly of the State of Illinois respectfully represents that the construction of a canal uniting the waters of Lake Michigan with the Illinois river, will form an important addition to the con-

necting links in the chain of internal navigation, which will effectually secure the indissoluble union of the confederate members of this great and powerful Republic. By the completion of this great and valuable work, the connection between the north and the south, the east and the west, would be strengthened by the ties of commercial intercourse and social neighborhood, and the union of the states might bid defiance to internal commotion, sectional jealousy and foreign invasion. All the states of the Union would then feel the most powerful motives to resist every attempt at dissolution. To effect so great and desirable an object, your memorialists believe to be of sufficient importance to engage the attention and awaken the munificent patronage of a government whose principle of action is the promotion of the general welfare. Your memorialists are sensibly alive to the spirit of improvement that manifests itself in almost every section of our extensive country, and would fain lend a helping hand in so great and good a cause; their situation, however, forbids their doing much, without the aid of the federal government; into whose treasury almost all the funds whether brought hither by emigrants or earned by the industry of their citizens, are paid for the purchase of the public lands. While this state of things shall continue and the money thus paid into the treasury of the Union is taken out of our State, our people will not be able to engage in the glorious work of improving our common country. Ought the people of this State to stand by with folded arms and behold the great work of internal improvement progress in other states without making an effort to improve their own conditions, and at the same time advance the interest of our beloved country? A condition thus paralyzed, is at war, not only with our interests, but with the best feelings of our hearts. Did this State possess the public domain lying within its bounds, as in the case with the older members of the confederacy, your memorialists would not appear before your honorable body to solicit aid in this important work. If, as your memorialists believe, the construction of this canal would be highly beneficial to the Union at large; if the receipts into the treasury of the United States would be augmented by the increased sales of public lands; and if the interest of this State would be also advanced thereby; is it unreasonable to apply to a paternal government for assistance in the promotion of such beneficial ends? It is unnecessary for your memorialists to enlarge on the great advantages of this canal to the

Union, in the facilities to be afforded in the event of a war with either the Indian tribes inhabiting our frontier, or the British nation. Your honorable body is aware that this State is situated on the borders of an Indian country, filled with numerous and powerful tribes of the sons of the forest. If our country should be again engaged in war, the saving of expense in the transportation of munitions of war, would alone defray the expense of the contemplated canal, and justify the United States in making a liberal appropriation for its construction. Your memorialists do not, however, ask your honorable body to appropriate money out of the treasury to aid them in this work; they only ask for a tract of land, through which the contemplated canal may pass, and which, for a series of years, will be wholly unproductive to the government unless the canal shall be commenced under auspices favorable to its completion; in which event all the land in the vicinity would immediately become available to the United States. Your memorialists sincerely believe that a liberal appropriation of land for this object, would, even in a pecuniary point of view be of immense importance to the treasury of the Union. The public lands in the vicinity would not only sell, but at a considerable advance upon the minimum price. Should this opinion be correct (and does not experience justify it?) the United States would be gainers by the proposed donation to the State. Your memorialists further state that at their last session, they passed an act of incorporation, upon very liberal terms, authorizing a company to construct the projected canal; but the remoteness of the country from the residence of capitalists, has prevented them from engaging in the work. At their present session, your memorialists have repealed the charter; and their only hope of soon beginning the work depends upon the liberality of your honorable body. Your memorialists have caused the route to be explored and estimates to be made of the probable expense of the work; from which it appears that the cost of constructing the canal will not be less than $600,000 and may possibly amount to $700,000. To the end, therefore, that your memorialists may be enabled to commence and complete this great and useful work, we pray your honorable body to grant to this State the respective townships of land through which the contemplated canal may pass; the avails of which to be appropriated exclusively, to the construction of said canal, upon such terms and conditions as to your honorable body may seem proper.

"An Ordinance for Cleansing the Chicago River and Appropriating the Proceeds of Two Hundred and Fifty Bonds Therefor.

Section 1. Be it ordained by the Common Council of the City of Chicago (June 5, 1865), That the plan of the board of public works for cleansing the Chicago River and its branches by cutting down the summit of the Illinois and Michigan Canal below the level of Lake Michigan so as to draw from it at a low stage of water in the lake not less than twenty-four thousand (24,000) cubic feet of water per minute, is hereby approved, and said board are hereby authorized to execute said work.

Section 2. That the board of public works are hereby authorized and empowered for the purpose of prosecuting the work described in the previous section, to make any contract necessary to carry into effect such purpose with the trustees of the Illinois and Michigan Canal, in conformity with and subject to the general provisions of the city charter.

Section 3. That as a temporary expedient for cleansing the South Branch of the Chicago River, the said board are hereby authorized and empowered to contract with the said trustees for the pumping from the river into the canal, by the hydraulic works at Bridgeport, and discharging through the canal of such amount of water as shall be found necessary and practical for such purpose.

Section 4. That for the purpose of carrying out the improvement specified in the foregoing sections, the board of public works be and they are hereby authorized to issue 250 bonds of the denomination of $1,000 each, to be dated July 1, 1865, and payable in New York, twenty-five years after the date thereof, with coupons for interest, at the rate of seven per centum per annum, payable semi-annually in New York; the said bonds to be issued in conformity with the provisions of an act of the General Assembly of the State of Illinois, approved February 15, 1865, and entitled 'An act to amend an act entitled an act to reduce the charter of the City of Chicago, and the several acts amendatory thereof, into one act, and to revise the same,' approved February 13, 1863."

Exhibit "H" to Answer.

Application of the Sanitary District for the Improvement of the Chicago River.

Chicago, June 16, 1896.

To the Honorable Daniel S. Lamont, Secretary of War, Washington, D. C.

Dear Sir: The work of The Sanitary District of Chicago has progressed so far that it is now necessary for us to enter upon that which must be done in the Chicago River to make available the artificial channel which we have under construction from Robey Street, Chicago, to Lockport in Will County, twenty-eight miles distant.

Our connection with Lake Michigan must be through the Chicago river with the West Fork of the South Branch of which we make a junction at Robey Street. We send herewith a map showing in a general way our plans for improving the Chicago River by widening and deepening at the points indicated thereon by red hatchings and by figures which refer to explanation, given in the legend on the map. It is desired to so correct and regularize the cross section of the river as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of one and one-quarter miles per hour. The cross section necessary to accomplish this can be obtained throughout the greater part of the distance between Monroe Street and Robey Street, by dredging the river to a depth of 20 ft. at mid stream, with 12 ft. at dock lines and a uniform slope away from docks of one foot in five, so that the full depth would be reached forty feet from the dock lines; but there are places so narrow that this cross section can only be obtained by widening the river; and again the depth to be obtained in the vicinity of Van Buren Street is limited by the height of the crown of the tunnel. To obviate this difficulty it is purposed to secure the requisite cross section by constructing a by-pass to the west of the bridges at Adams, Jackson and Van Buren Streets, as indicated. We ask your permission to proceed with the work upon the lines indicated and so far as is consistent with propriety the co-operation of the United States Engineering Department.

Awaiting your favorable reply, and holding ourselves ready to respond to any call from you for fuller information as to our plans, I am (map opposite, Exhibit H)

Yours respectfully, (Signed) B. A. Eckhart, President.

Permit for the Improvement of the Chicago River
(Permit of July 3rd, 1896)
Improvement of the Chicago River

July 3, 1896.

Sir: I have the honor to acknowledge the receipt of your letter of 16th ultimo, requesting permission to make certain changes in the capacity of the channel of the Chicago River for drainage purposes at points indicated on the map accompanying the application, and in reply beg to say that upon investigation it is found that the permission requested can be granted upon the following conditions:

1. That while the general plan is approved, the Sanitary District of Chicago must furnish plans in triplicate on an enlarged scale showing each proposed new bridge, each by-pass and each new dock or wharf proposed to be built, in order that the Secretary of War may act intelligently in each case.

2. That this authority shall not be interpreted as approval of the plans of the Sanitary District of Chicago to introduce a current into Chicago River. This latter proposition must hereafter be submitted for consideration.

3. That it will not cover obstructions to navigation by reason of this work while in progress or when completed.

4. That the United States shall not be put to expense by reason of this work.

5. That this authority will expire by limitation in two years from date unless extended.

Very respectfully, (Signed) Joseph B. Doe, Acting Secretary of War. B. A. Eckhart, Esq., President the Sanitary District of Chicago, Rialto Building, Chicago, Ill.

Exhibit "J" to Answer.

Security Building
The Sanitary District of Chicago

Chicago, April 26, 1900.

To the Honorable the Secretary of War.

Sir: The Sanitary District of Chicago, a municipal corporation organized and existing under the laws of the State of Illinois, respectfully represents that, by the laws of the State of Illinois and the charter of this petitioner, it is authorized to enter upon, widen, deepen and otherwise improve any navigable stream, river or other waterway. That in pursuance of the power conferred upon it by the statutes of the State of Illinois, and in the performance of the duties enjoined upon it by the act of the Legislature authorizing its creation, and under which it is acting, it has been determined to improve the Chicago River by widening and deepening the same and to the end that such action on the part of your petitioner may be conformable to law and the statutes of the United States in that behalf, it hereby makes application for permission to make the changes, alterations and improvements in said Chicago River from or near Lake Street in the City of Chicago to or near Ashland Avenue in the City of Chicago, said work to conform to the plan and specifications as follows:

(a) A map herewith exhibits the existing boundaries of that part of the South Branch of the Chicago River which it purposes and desires to improve.

(b) The work to be done contemplates widening the river to a width of two hundred (200) feet between dock lines, except in so far as bridge abutments may project into the stream outside of the new dock lines; said widening in all cases to be made with a view of improving the navigability of the stream.

(c) The work to be so done as to ultimately permit excavation of the river bed to a depth of thirty (30) feet below water surface throughout the central portion of the stream.

(d) The widening of the river is to be so disposed that the effect will be to produce a straighter channel than now exists and, furthermore, to result in a continuous dock line having straighter alignment and being better

disposed for navigation than the docks which now exist.

(e) The work to be done is to be prosecuted progressively as to time. The rate of progress being limited by the rapidity with which right of way may be acquired and the resources for the execution of the work to be made available. The modification and alteration of said river as above indicated will greatly benefit navigation in said river. Your petitioner, therefore, respectfully requests that the plan of improvement as above outlined be approved by you.

Awaiting as early a reply as practicable under the circumstances, your petitioner has the honor, to be.

Very respectfully yours, The Sanitary District of Chicago, by William Boldenweck, President. Attest: Joseph H. Haas, Clerk.

Exhibit "J-1" to Answer.

Chicago, June 7, 1900.

To the Honorable, the Secretary of War.

Sir: Under date of April 26, 1900, the Sanitary District of Chicago had the honor to address a communication to you containing an outline of the proposed improvement of a portion of the South Branch of the Chicago River. Accompanying the letter was a map showing the location of the South Branch of the Chicago River, the bridges spanning said river and, also, the width of the stream along the entire course of the South Branch of the river. Since that date the Sanitary District of Chicago passed an ordinance for the improvement of the South Branch of the Chicago River from the south line of Twelfth Street to the east line of Ashland Avenue, so as to make said South Branch, between the lines aforesaid, of a uniform width of two hundred (200) feet; the work to be done so as to ultimately permit excavation of the river bed to a depth of thirty (30) feet below water surface throughout the central of said stream, in accordance with the plans adopted by the Board of Trustees of the Sanitary District of Chicago, a copy of which plans is hereto annexed. The ordinance refered to being marked Exhibit "A," with this letter; and the maps showing the plans of the proposed improvement being marked Exhibit "B." The maps are in two sections, known respectively as No. 2 and No. 3.

The Sanitary District of Chicago is a municipal corporation, organized and existing under the laws of the State of Illinois and by the laws of said State and the charter of said Sanitary District, it is authorized to enter upon, deepen, widen and otherwise improve any navigable stream, river, or other water-way; and that in pursuance of the power conferred upon it by the statutes of the State of Illinois and in performance of the duties enjoyed upon it by the act of the legislature authorizing its creation, and under which it is acting, it determined upon said plans outlined in the enclosed ordinance and further illustrated by the maps hereto annexed; and the said Sanitary District, in compliance with the Statutes of the United States, hereby makes application to you for permission to make the changes, alterations and improvements in said South Branch of the Chicago River, from the south line of Twelfth Street to the east line of Ashland Avenue.

Awaiting as early a reply as practicable under the circumstances, your petitioner has the honor to be,

Very respectfully yours, The Sanitary District of Chicago, by William Boldenweck, President. Attest: Joseph F. Haas, Clerk. (Exhibits K1, K2, page opposite.)

OPINIONS, ORDERS AND ASSIGNMENT OF ERRORS.

Between the filing of the Bill of Complaint in the Calumet suit, March 23, 1908, and December, 1914, and on April 25 and 26, 1923, evidence was offered by both parties before a Commissioner appointed by the Court upon the various issues involved in the pleadings. It was stipulated that evidence offered in either suit by either party, material or relevant to the issues in the other suit should be treated as if offered and presented in such suit. By agreement, the causes were submitted upon the evidence which was printed and upon printed briefs and arguments on behalf of

both parties to Honorable Kenesaw Mountain Landis, one of the Judges of the District Court of the United States for the Northern District of Illinois, Eastern Division, February 15, 1915. The evidence will be hereafter described and narrated. June 19, 1920, Judge Landis having called the attorneys for both parties together, delivered an oral opinion, announcement or direction for decree. A stenographic transcript of this opinion appears in the certificate of evidence filed June 29, 1923, after the order of injunction in said cases was entered. The oral opinion is as follows (Vol. VIII, pp. 149-152):

OPINION OF JUDGE LANDIS IN SANITARY DISTRICT CASES.

June 19, 1920.

"I have sent for you gentlemen to dispose of the Sanitary District cases. Before taking up these cases, just a word about time and delay. Six years was spent after these cases were filed in taking testimony, and about six years has passed since the cases were submitted to me on briefs. The six years that was taken up while taking testimony was all necessary. The delay that has occurred since the matters have been submitted to me have been the result of the exercise of my judgment. First, that during the war period, in view of the international questions possible, I thought it was better that this matter should continue just as it was, and secondly, since the war I have deferred entering this order with the understanding that there was a possibility of a composition of differences here that would enable the questions to be permanently adjusted along lines which I have been told were suggested by the Sanitary District to the War Department and the Canadian Government. I have held the matter, however, as long as I think proper on that theory and shall enter an order.

The bills were filed under legislation authorizing the United States to receive the injunctive power of the court as against obstruction of navigable waters and impairment of the navigable capacity of navigable waters. The averments, so far as I need to deal with the averments here now, are that the Sanitary District proposes to take an amount of water—is taking an amount of water—proposing to take more, the taking of which will result in such impairment and such obstruction. Specific-

ally, the impairment complained of most important in my view, is the impairment of the navigable capacity of the Great Lakes, excepting Lake Superior. The theory of the bills is—the charge is that such impairment by the district as is charged in the bills, without the consent of the Federal authorities at Washington, which consent is authorized and provided for by the Federal legislation, as I said before, entitles the government to an injunction. The defense of the Sanitary District is, first, that there is no impairment and no obstruction, and primarily, secondly, if there is an impairment or an obstruction, that it is necessary for the sanitation of this great populative territory. An examination of the proofs on the question of whether there is an impairment or not, an obstruction or not, that is to say, whether the taking of this water is felt or not, leads me to the conclusion that there is a lowering of the surface of this lake. In making that statement I have in mind the variation of the lake levels, traditional variation of the lake levels, known to all men that know anything about it. All that time finding that there is a lowering of the lake level, yes. That the taking of this vast volume of water each minute of each hour of each day of each month of each year continued unceasingly, no evidence in this case discrediting the fact, and has entirely resulted in the lowering of the level of the lake, and has resulted in changing the current of the Chicago River and reversing the current of the Chicago River. Now that the variation is only a matter of inches in the level of Lake Michigan, it is without doubt in my judgment, on the evidence in the matter, a matter of inches, and being a matter of inches, even though it be no more than three or four, having in mind the state of proof as to the depth of the harbors in the Great Lakes, it is directly an impairment of navigable capacity, and by leaving the bottom of the harbors that much closer, the water is the creation of an obstruction to the navigable waters of the United States; in other words, the question of fact—whether there is an impairment or obstruction here, are beyond controversy and beyond question, but the fact is clearly established that there is such a change in this lake level, in my judgment, so that in low lake level time the level is lower and in high lake level time it is less than it would be but for this diversion.

Q. How many cubic feet per minute now?

A. Just at present I think about 8,500 per second. 480,000 cubic feet per minute, that is approximately.

The diversion is 480,000 cubic feet per minute. The finding of the court is, on the evidence in this case, that that has resulted in the lowering of the lake level and the reversal of these currents, which latter fact is not controverted, and on the evidence in the case that the lowering is an impairment, as I said before, an impairment of navigable capacity, even though it amounts to no more than three or four inches, and as to the lowering to that extent there could be no controversy on the record, so on that fact the court's finding is against the contention of the defendant on the proposition that this is a necessary thing for the salvation of this community, that is, without this water this community will be at the mercy of diseases and germs from which it suffered before this diversion began and from which it has by this diversion been practically relieved of, as shown by statistics. The court has complied with the rule of law, that navigable rights are paramount, and even though the district is driven to the necessity of making some other provision, granting that the War Department and Congress should refuse to give that contention to this question of sanitation, it is entitled to the law which is in force in this room on me, which I must obey, that a navigable right is paramount, and that in the last analysis should Congress and the War Department in consideration of all these matters decline to permit the necessary diversion, the burden is on the District of providing some other method of relief; in other words, the defense that is necessary for the purposes of sanitation as against the rule that a navigable right and navigation right is a paramount right, is immaterial.

I had hoped, as I stated at the beginning, that there might be a composition of this thing. The Judge has no right to have personal feelings, but I live in this community, and it was my hope that there could be devised a program that would enable this district to have the benefit of this water, as much as it needs, that will give to the country this water in the solving of this problem of navigation.

There will be an order striking or sustaining the exceptions of the plaintiff, certain paragraphs of your answer setting up this sanitation defense. There will also be another sustaining the operation of this order which I am entering here this morning until 30 days after the Sanitary District has an opportunity to present to the Supreme Court of the United States an application for a supersedeas against high water, that is 30 days after

the date fixed for the meeting of the Supreme Court in October. The order will not go into effect, it will be suspended until 30 days after the Supreme Court meets in October. That is plenty of time, is it not? A. Yes, sir. I think that is plenty of time. I have considered that is enough. I wanted to make no mistake. You can form it in a way so that you will have a final order to appeal from. You have got to have that in mind. You may draw an order effective 30 days after the Supreme Court meets.

I omitted to mention one matter here which is not important, except the control of the Federal Government over this question has been recognized from the beginning by the Sanitary District itself before the diversion began and continuously down until what was that year when they attached that order, 1909? A. I think 1907 or 1908.

From the beginning, prior to the beginning of the diversion and down to 1907 or 1908, the constant attitude of the Sanitary District was a recognition of the control of the Federal Government over this whole question, everything that was done by the Sanitary District in the way of diversion being in a permit granted by the War Department on application of the Sanitary District to that end. The Sanitary District shall have an opportunity to apply for further relief to the War Department at Washington. Under no circumstances does this order go into effect now. Make that 60 days, and you may put in it, if it does not destroy the appealability of the order, you may put in a provision retaining me in control. The thing that the Government wants, at least the court wants, being a citizen of Chicago, the thing I want is water without microbes. That is why I have held your lawsuit."

July 12, 1920, subsequent to Judge Landis' delivering the opinion as aforesaid, the Sanitary District presented a motion entitled

"Motion for Reconsideration of Oral Opinion and Oral direction of the Court concerning the form of decree in said two causes, together with grounds of said motion." The Motion is in part, as follows (Vol. VIII, pp. 152-167):

"Now comes The Sanitary District of Chicago, defendant, in said two causes, by C. Arch Williams and

Edmund D. Adcock, its attorneys, and moves the court that it reconsider its oral opinion and oral direction heretofore announced concerning the form of decree to be entered in the said causes, and that the court direct that The Sanitary District of Chicago, defendant, be enjoined, only, from withdrawing or diverting from Lake Michigan, through its various works now constructed or under construction, more than ten thousand cubic feet of water per second from Lake Michigan on condition that if the Congress of the United States, or other competent governmental authority, provides for the construction of, in the St. Clair, Niagara or St. Lawrence Rivers, or in one or all of them, works to compensate for any diminishing levels of the Great Lakes and connecting waters, due to the diversion or withdrawal of ten thousand cubic feet of water per second from Lake Michigan by The Sanitary District of Chicago, then The Sanitary District of Chicago shall defray the expense and pay the cost of the construction and maintenance of any such works upon request therefor by the United States of America. In connection with said motion, and as a part thereof, the defendant hereby offers and agrees to defray the expense or pay to the United States upon demand the cost of the construction and maintenance of the works of the character above described in accordance with an ordinance of the Board of Trustees of The Sanitary District of Chicago passed and approved by said Board on the 8th day of July, A. D. 1920, a copy of which said ordinance is hereto attached and marked Exhibit "A," a certified copy of which is here ready to be produced in court. In support of said motion, and as grounds therefor, the defendant alleges and shows the following:"

As grounds for the said motion, the defendant recited the institution of the suits, the purpose of the complaint in the main channel suit filed October 6, 1913, and that the ground for the injunction sought was that the diversion of water would lower the levels of the Great Lakes and connecting waters, thereby injuring navigation and changing the navigable capacity of such navigable waters of the United States.

3. It is further set forth that it is an admitted and undisputed fact on the record in said causes that works may be installed in the St. Clair, Niagara and St. Lawrence Rivers,

which will compensate for the lowering of the lake levels due to diversion at Chicago of 10,000 cubic feet per second.

A portion of the River and Harbors Act of June 25, 1910, was set forth as follows:

> "The Secretary of War shall appoint a board of five members, to be composed of four engineer officers of the army and one civil engineer, taken from civil life. * * * Said Board shall report upon * * * such measures as may be required to properly preserve the levels of the Great Lakes and to compensate, as far as practicable for the diminishing level in said lakes and the connecting waters thereof by reason of any diversion of water from Lake Michigan for the maintenance of the proposed waterway herein described, or diversion for any other purpose."

The motion further stated:

> "The Board of Engineers, provided for by said Act of Congress, so appointed, made an investigation and its report was submitted to the Board of Engineers for Rivers and Harbors on August 15, 1913. The Board of Engineers for Rivers and Harbors report, reviewing the report of the special board, is dated December 16, 1913. It is signed by General William M. Black, then senior member of the Board, who was later and for a number of years Chief of Engineers of the United States army. Concerning the Chicago diversion, the Board of Engineers for Rivers and Harbors, in its report stated:
>
> 'Further, the Board believes that the total volume of water to be diverted from the natural discharge channels of the lakes should be definitely fixed by Congress; that a project with estimate of cost for works necessary to compensate for such diversion should be prepared to the satisfaction of the Chief of Engineers, and the Secretary of War; that before any diversion is made beyond that at present existing, the State of Illinois shall transfer to the Secretary of War the funds necessary for such works as given by approved estimate of cost that the work shall be built by the United States with the funds so provided and that the control and maintenance of such works shall be in and at the cost of the United States.'
>
> The Special Board's report upon the subject of compensating for diminished or diminishing lake levels is as follows:

'To restore the diminished levels in the lakes by constructing contracting works in their outlets does not, however, present any serious difficulties. A careful discussion of the proper locations and dimensions of such works is also given in Appendix A.

At the foot of Lake Ontario the closure of the Gut channel of the Galops Rapids by the Canadian Government has had the effect of raising the level of Lake Ontario an amount nearly equal to the computed lowering of the lake by a diversion of 10,000 second feet at Chicago, and no compensation is at present deemed necessary to restore former conditions in this lake.

In Appendix A it is proposed to diminish the outflow of Lake Erie by the construction of three submerged weirs in Niagara River in the vicinity of Squaw Island, which would average about 4.2 feet in height and would contain about 15,000 cubic yards of masonry. The estimated cost is $150,000.

To raise the level of Lakes Michigan and Huron submerged weirs are proposed in St. Clair River, covering 3 miles of river below the mouth of Black River at Port Huron. The weirs as suggested in Appendix A have a height of from 5 to 6 feet above the river bed, contain about 65,000 cubic yards of material, and their estimated cost is $325,000. It is computed that these weirs will increase the velocity of the water flowing over them slightly (from a mean of 3.28 feet to 3.89 feet per second), but, on the other hand, above the mouth of Black River the river slopes and velocities which are now excessive will be diminished, and navigation on the whole will be considerably benefited.

The Chicago diversion has no effect on Lake Superior.

Compensation for the loss of elevation on Lakes Michigan, Huron and Erie, and their connecting waters, due to an assumed diversion from Lake Michigan of 10,000 second feet, will by the plan above outlined involve an expenditure of about $475,000, to which should be added an amount for the maintenance of the weirs, estimated at about $15,000 per year, the total cost being much less than the cost of restoration of depths by dredging. It is the opinion of the board that while other plans have been proposed compensation by fixed contraction works similar in general to those above described affords the cheapest and most satisfactory method of preserving the levels of the Great Lakes.'

Said report is signed by W. H. Bixby, Brigadier General, U. S. Army, retired, President of the Board; C. McD. Townsend, Colonel, Corps of Engineers, U. S. Army; C. Keller, Major, Corps of Engineers, U. S. Army; J. B. Cavanaugh, Major, Corps of Engineers, U. S. Army; and John Bogart, Civil Engineer.

* * *

4. On June 30, 1917, the Congress of the United States by joint resolution authorized and directed the Secretary of War to

"Make a comprehensive and thorough investigation, including all necessary surveys and maps, of the entire subject of water diversion from the Great Lakes and Niagara River, including navigation, sanitary and power purposes, and the preservation of the scenic beauty of Niagara Falls and the rapids of Niagara River, and to report to Congress thereon at the earliest practicable date."

Accordingly, the Chief of Engineers, by direction of the Secretary of War, authorized the Division Engineer, Lakes Division (Col. J. G. Warren, Corps of Engineers, U. S. Army), to make and prepare a report upon all the diversions of the Great Lakes. This report was recently submitted to the Board of Engineers on Rivers and Harbors, and, on June 3, 1920, * * * The said report found that there were many diversions of the waters of the Great Lakes which effected the lowering of lake levels, and particularly the level of Lake Erie—such as the diversions at Niagara for power purposes, the diversion of 4,500 cubic-seconds feet for power purposes through the Welland Canal and other diversions, including the Chicago diversion; that the Chicago diversion of 10,000 cubic feet per second would produce approximately 55 per cent of the entire lowering of Lake Erie. The report further finds that any diminished or diminishing levels of the lakes due to the Chicago diversion, or any other diversion, may be compensated for by the construction of works in the St. Clair and Niagara rivers of the character described in said report entitled "Final Report, Waterway from Lockport, Ill., to the Mouth of the Illinois River," or by the construction and operation of so-called "regulating works" in the Niagara River, which said works would consist of dams which may be moved at will to regulate the levels of Lake Erie. It was recommended that The Sanitary District be allowed and permitted to withdraw from Lake Michigan 10,000 cubic second-feet of water and that works to compensate for any diminished

or diminishing lake levels should be built at the expense of The Sanitary District.

5. The treaty between the United States and Great Britain of 1909, relating to Canadian boundary waters, provided that there may be diverted from the Niagara River above Niagara Falls, on the Canadian side, water to the extent of 36,000 cubic feet per second and on the American side, 20,000 cubic feet of water per second. The reason that the United States was only permitted to divert 20,000 cubic second-feet as compared with the Canadian right of 36,000 second-feet was because the United States was charged with the diversion of 10,000 second-feet at Chicago. Canada, therefore, can make no objection. The International Waterways Commission was organized and appointed pursuant to the joint action of the Congress of the United States and the Parliament of Canada. Canada and the United States each appointed three members thereof. The purpose of the organization of the International Waterways Commission was, among other things, to recommend the form of a treaty between the United States and Great Britain concerning the Canadian boundary waters. On April 25, 1906, the Canadian section of the International Waterways Commission made a report to the Commissioner of Public Works of Canada, as follows (proceedings I. W. C., page 333):

"At Chicago the Americans had built a drainage canal which, when in full operation will use about 10,000 cubic feet of water per second.

The quantity of water required for the purpose of a ship canal is comparatively small, but the character of this drainage canal at Chicago is such as to involve the continuous flow of water, which will have the effect of lowering Lake Michigan, by over 6 inches and Lake Erie by 4½ inches. The nature of this work may be judged when we state that the expenditure will be over $40,000,000 and that power works are in the course of construction on the canal which will generate some 30,000 H. P.

As the diversion from Lake Michigan to the Mississippi River is of a much more serious character than the temporary diversions from the Niagara River, it is felt that the amount of water taken on the American side of the Niagara River should be limited to 18,500 cubic feet per second. * * * It is exceedingly important in the interest of navigation, both to ourselves and the people of the United States, that the diversion by way of the Chicago drainage canal should be limited. * * * If our pro-

posal is carried out the diversions will be about as follows:

Diversions on the American Side

	Per Second Cubic feet
Niagara Falls	18,500
Chicago Drainage Canal	10,000
Total	28,500

Diversions on the Canadian Side

Niagara Falls and on the Niagara Peninsula	36,000

It is quite apparent that no further diversion can be made on the Niagara River without injury to the scenic effect of the Falls as a whole, and there should be no further diversion from Lake Erie or any other of the waters of the Great Lakes system, which will be injurious to navigation. Your Commission is, therefore, of opinion that the time has come when it is desirable to make a treaty limiting these diversions. * * * Therefore this Commission recommends that a treaty be had between the United States and Great Britain, in framing which, it should be recognized that * * *

Permanent or complete diversions of such waters are wrong in principal, and, therefore, should hereafter be absolutely prohibited. The diversions by the Chicago drainage canal should be limited to the use of not more than 10,000 cubic feet per second. * * * This would give an apparent advantage to Canadian interests, but as the diversion is not of serious injury to the Falls and does not materially affect the interests of navigation, it is more than counter-balanced by the complete diversion of 10,000 cubic feet by way of the Chicago drainage canal to the Mississippi River.

On May 3, 1906, the International Waterways Commission, by report signed by all members, made a report as follows (proceedings I. C. W., 339):

"The Commission has made a thorough investigation of conditions existing at Niagara Falls and the two sections have presented reports to their respective governments setting forth these conditions, to which attention is invited. The following views and recommendations are based upon a careful study of the facts and conditions set forth in these reports * * *

2. While the Commission are not fully agreed as to the effect of diversions of water from Niagara Falls, all are of the opinion that more than 36,000 cubic feet per second on the Canadian side of the Niagara River, or on the Niagara Peninsula, and 18,500 cubic feet per second on the American side of the Niagara River, including diversions for power purposes on the Erie Canal, cannot be diverted without injury to Niagara Falls as a whole.

3. The Commission, therefore, recommends that such diversions, inclusive of water required for domestic use or the service of locks in navigation canals, be limited on the Canadian side to 36,000 cubic feet per second, and on the United States side to 18,500 cubic feet per second (and in addition thereto, a diversion for sanitary purposes, not to exceed 10,000 cubic feet per second, be authorized for the Chicago drainage canal), and that a treaty or legislation be had limiting these diversions to the quantities mentioned.

The effect of the diversion of water by the Chicago drainage canal upon general navigation interests of the Great Lakes' system will be considered in a separate report. * * * The following principles are suggested * * *:

Permanent or complete diversions of navigable waters or their tributary streams should only be permitted for domestic purposes and for the use of locks in navigation canals."

On January 4, 1907, the International Waterways Commission made a special report, signed by all the members, entitled:

'The Chicago Drainage Canal—Joint Report of the International Waterways Commission.'

Among other things in said report, the said Commission stated:

'There appears to be a tacit general agreement that Chicago needs, or will need about 10,000 cubic feet of water per second for sanitary purposes and that the city should have it without further question. * * * We therefore recommend that the government of the United States prohibit the diversion of more than 10,000 cubic feet per second for the Chicago drainage canal.' "

The Motion stated that the Secretary of War's permit of May 8, 1899, is limited only by the capacity of the channel to 10,000 cubic feet of water; that the limitation of flow thereafter made, was solely because of the then narrowness and

shallowness of the Chicago River and its South Branch and West Fork; that thereafter, with the consent of the Secretary of War and for the purpose of enlarging the cross section and channel of the Chicago River and its branches to provide a flow of 10,000 cubic seconds feet, the Sanitary District improved the river by deepening the channel from 17 to 26 feet, and widening it at all points to 200 feet so that its channel capacity was the amount of water desired to be withdrawn and required; that the cause for the limitation of the flow to 4,167 cubic seconds feet having been eliminated, the order of the Secretary of War so limiting it, should be considered of no force and effect.

The motion further set forth (Rec. Vol. VIII, p. 164):

"(7) The diversion of at least 10,000 cubic second-feet of water from Lake Michigan is essential for the sanitary needs and requirements of the population within the the limits of The Sanitary District, which includes that of the City of Chicago and its suburbs, comprising a population of approximately 3,000,000 people. The primary purpose of The Sanitary District is to construct and operate works to provide a pure drinking water supply for this population. The plans for the works of The Sanitary District were formulated and recommended by a commission of engineers, pursuant to an ordinance of the City of Chicago, known as "Drainage and Water Supply Commission." This commission studied the matter for two or three years and finally recommended the diversion of the drainage and sewage of Chicago and its environs to the Desplaines River, together with a sufficient amount of water from Lake Michigan (20,000 cubic feet per minute for each 100,000 population) to oxidize the sewage and waste. This Commission's report was made in 1887 and The Sanitary District Act was passed pursuant to the recommendations of that Commission at the next session of the Legislature, and the District has expended upwards of $100,000,000 in the construction of these works. They have accomplished practical results. There was not at the time the Commission made its report, and there has not been since that time, any other practical method that could have been adopted to accomplish the purpose of these works—namely, the protectection of the water supply. The record in this case shows that the art of artificially purifying sewage has been for years, and is now, in a state of uncertainty, and there is

no plan for artificially purifying sewage that engineers agree is feasible and practical, and will with any certainty serve for a considerable period of time in the future—and this is particularly true when dealing with great metropolitan populations.

The basis, therefore, of The Sanitary District's diversion works is the reversal at all times of the Chicago River, into which a large amount of sewage is emptied from sewers serving the people of Chicago and its suburbs. The maximum run-off of the Chicago River drainage area is 10,000 cubic second-feet. Obviously, if the capacity of the main channel of the District were less than 10,000 second-feet, the Chicago River would flow into Lake Michigan at certain flood times. The withdrawal of water from Lake Michigan must, therefore, be the same amount, because it would be impossible, if the flow were limited to 4,167 feet, or any amount materially below the 10,000 second-feet, to change the flow from the the limited amount to the maximum run-off of the drainage area in time to keep the water from going into Lake Michigan. This is demonstrated by testimony of witnesses in this case and it is recognized as a fact by the report of Col. Warren, Division Engineer of the Lakes Division, above mentioned. The limitation of the flow to 4,167 second-feet, or any amount materially less than 10,000 second-feet, would, therefore, require the absolute and complete purification of all sewage within the limits of the District, so that if any effluent found its way into Lake Michigan, it would not affect the water supply.

There was presented in this case estimates of the cost of constructing artificial purification works to completely purify the sewage and drainage. These estimates were made in the year 1913. The total cost of constructing these works, which would require a great number of years to complete, was from $75,000,000 to $100,000,000. The figures were made with reference to the cost of materials, labor, etc., as of the year 1913. Since that time the cost of labor and materials for similar works has increased approximately 100 per cent, so that to install the works which would be made necessary by reason of the limitation of the flow to 4,167 second-feet, would be from $150,000,000 to $200,000,000. The cost of operating and maintaining these works annually was also estimated, and the estimates were upwards of $5,000,000 per annum. The annual operating and maintenance cost would now, according to present prices of labor and materials, much exceed that amount.

It is also shown in the record in this case that it would be impossible for the District or this community to raise the money necessary to construct these works within any reasonable time, unless constitutional amendment should permit greater bonding power.

In addition to the amount which the District would be compelled to expend by virtue of the limitation of flow to 4,167 second-feet, it would lose the greater portion of the investment that it has already made in the present diversion works.

Furthermore, it is probable that any works which the District might install for the purification of sewage and drainage would, within a very short time, have to be discarded and thrown aside for some other works upon a different plan. Indicative of the changes in the art of artificially purifying sewage that have taken place we refer to the fact that it was only five years ago that most sanitary engineers believed that the best method to be used was the Imhoff Tank system. In these tanks a certain amount of sewage was allowed to settle and the effluent drawn off to run through what are called "sprinkling filters," by which the effluent from the Imhoff tank was, by means of a nozzle, sprayed over crushed rock of several feet in thickness. Lately, sanitary enginers have reached the conclusion that such method is not proper but that what is known as the "activated sludge" system should be used. This system contemplates the passing of the sewage and drainage at low velocities through tanks, which tanks are provided at the bottom with perforations so that a vast amount of air may be pumped through the sewage and thereby the sewage be purified.

If the District were limited now to the withdrawal of 4,167 second-feet, at many times during the year the Chicago River would flow into Lake Michigan, carrying with it a vast amount of sewage. At and prior to the time the Drainage Canal was opened and placed in operation, the death rate per year from typhoid fever was 75 per 100,000 population. Occasionally there would be epidemics, when the rate would be 190 per 100,000. Since the opening of the Drainage Canal there has been a steady reduction in the death rate per year from typhoid fever, with no epidemics, so that now the death rate from typhoid fever is less than 1 per annum per 100,000 of population. According to Hazen's theorem, where there is an increase of 1 per annum in death rate from typhoid fever, there is an increase of 3 from other kindred disease; and the same theorem applies conversely to a decrease. The

limitation to 4,167 second-feet would produce intolerable conditions in the Illinois River, because of the fact that the principal amount of the sewage of Chicago and its suburbs would be delivered to the Desplaines and Illinois Rivers without the necessary pure water for oxidization and purification purposes. All fish life would be destroyed throughout the entire course of said river and the fish industry along the Illinois River is one of the principal industries of the state. The conditions above mentioned that would result from the limitation of flow to 4,167 second-feet would continue until works were installed to practically purify a very large portion of the sewage and drainage arising within the limits of The Sanitary District, and it would continue to a certain extent until the works were installed to purify all sewage and drainage.

8. Since the drainage Canal was opened, January 17, 1900, all boats that were then navigating the Great Lakes and its connecting waters are not interfered with in any respect, by a less depth due to lowering of lake levels. All boats which the United States claims are affected—those owned by the Pittsburgh Steamship Co., a subsidiary of the United States Steel Corporation—were constructed since that time. All the critical points of navigation of the Great Lakes have been, since the opening of the Drainage Canal, deepened or improved, and the record in this case shows that the reference plane for the improvement of 1903, which included practically all the connecting channels, was made approximately 6 inches lower because of the diversion at Chicago—so that, the navigation interests have not been injured. They have the same depth of water that they would have had if the diversion had not existed.

9. The Sanitary District here and now offers and agrees to pay to the United States the amount of money necessary to construct, operate and maintain the compensating works which will off-set or compensate for any damage due to the diversion at Chicago. These works the Federal engineers have said may be installed and will accomplish the purpose named. If they were installed and placed in operation, the only ground of the Government for seeking the injunction here would be removed. The expense would be practically nothing as compared with the financial burden that would be placed upon the District if it is enjoined from withdrawing more than 4,167 second-feet of water, or any amount materially less than 10,000 second-feet. The only thing that the Government would have to do in order to accomplish the instal-

lation of the works would be to provide for their construction, operation and maintenance. The suggestion for modification of the opinion and direction of the Court with reference to the decree in these cases herein made points out the plain practical solution of this problem."

Exhibit "A" to Motion.

"An ordinance of the Board of Trustees of the Sanitary District of Chicago offering and agreeing to defray the expense of the construction of works in one or more of the outlets of the Great Lakes to compensate for any diminishing levels of the Great Lakes and connecting waters due to the diversion of 10,000 cubic feet of water per second from Lake Michigan by the Sanitary District of Chicago and authorizing the attorneys of the Sanitary District in the suits pertaining to said diversions now pending in the District Court of United States for the Northren District of Illinois, Eastern Division, to make and present such offer and agreement in open Court.

Whereas, there are now pending in the District Court of the United States, for the Northern District of Illinois, Eastern Division, two suits in equity instituted by the United States against The Sanitary District concerning the withdrawal of water from Lake Michigan by The Sanitary District of Chicago. The first suit was instituted in the year 1908 and pertains particularly to the construction and operation and withdrawal of water for the operation of the Calumet Sag Channel, an adjunct of the main channel of The Sanitary District of Chicago. The second suit was instituted in the year 1913 and seeks to enjoin The Sanitary District from withdrawing from Lake Michigan, through its various channels, including the Calumet Sag Channel then and now under construction, more than 4,167 cubic feet of water per second. The said suits have been tried together and submitted together upon briefs; and,

Whereas, the Honorable Kenesaw M. Landis, one of the Judges of said District Court of the United States, for the Northern District of Illinois, Eastern Division, before whom said cases have been pending, did recently render an opinion or direction for the entry of a decree in said cases, in substance, to enjoin The Sanitary District of Chicago, defendant in said cases, from withdrawing from Lake Michigan more than 4,167 cubic feet of water per second; and,

Whereas, various reports have been submitted pursuant to acts of The Congress of the United States by the Engineer Corps of the U. S. A., finding that the claim of injury to navigation arising from the lowering of lake levels because of the diversion from Lake Michigan of water at Chicago to the extent of 10,000 cubic feet of water per second, may be compensated for by the construction of fixed weirs or works of similar character, or by the construction and operation of movable dams in the St. Clair, Niagara and St. Lawrence Rivers, or one or all of them, and the expense of constructing said fixed weirs would, at the time the report was made, not exceed $475,000; and it was recommended that if The Sanitary District of Chicago should defray the expense of constructing such works, then they should be maintained by and at the expense of the United States; and, if such works were constructed and placed in operation, thereby the ground of the United States for securing the injunction herein would be removed; and,

Whereas, it is the opinion of the Board of Trustees that if The Sanitary District is enjoined from taking more than 4,167 cubic feet of water per second from Lake Michigan for sanitary purposes, it will be necessary to expend, in the construction of works to artificially purify sewage, supplement and aid the works diverting 4,167 cubic second feet of water upwards of $150,000,000, and the operation and maintenance of the same will exceed upwards of $5,000,000 per annum; and it is, further, the belief of the Board of Trustees of The Sanitary District of Chicago that it is doubtful whether such works, with said limited withdrawal of 4,167 cubic second feet of water will provide for the people of The Sanitary District of Chicago, which includes the population of Chicago and its environs, a safe drinking water supply, for the reason that it would be impossible, with said limited withdrawal, to keep the Chicago River at all times reversed so that it would not flow into Lake Michigan, carrying with it a large amount of sewage and drainage, and it is doubtful whether such purification works would accomplish practical results.

Now, therefore, be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. The Sanitary District of Chicago does hereby offer and agree to defray the expense, and pay to the United States Government the cost, of constructing and maintaining works to be installed at the outlet or outlets of any of the Great Lakes to compensate for any diminishing levels of the Great Lakes and connecting

waters, due to a diversion or withdrawal from Lake Michigan of 10,000 cubic feet of water per second by The Sanitary District of Chicago through its various channels and diversion works in the event The Sanitary District is not enjoined from diverting from Lake Michigan less than 10,000 cubic seconds feet of water.

Section 2. The said offer and agreement contained in Section 1 hereof is intended to embrace and cover not only the expense of constructing and maintaining fixed weirs or dams described in the report entitled 'Final Report of Waterways from Lockport to the Mouth of the Illinois River.' House of Representative's Document No. 762, 63rd Congress, 2d Session, but also any other works of similar character that may be planned or provided for by the Congress of the United States or by competent Governmental authority, or works known as "regulating works," consisting of movable dams or dams that may be moved from time to time, that may be planned or provided for by The Congress or other competent authority—such works having for their purpose compensation for any diminishing levels of the Great Lakes or connecting waters due to a diversion at Chicago of 10,000 cubic second feet of water; and the said The Sanitary District of Chicago offers and agrees to pay to the United States the expense of constructing and maintaining such works whenever the United States shall provide for such construction and make request for the payment of the amount of money necessary to construct and maintain the same.

Section 3. The attorneys for The Sanitary District of Chicago in said two suits above described, wherein the United States is complainant and The Sanitary District of Chicago is defendant, on behalf of The Sanitary District of Chicago, are hereby authorized, empowered and directed to present and make said offer in open Court in said causes, or in any other manner that the said attorneys may deem proper.

Section 4. The preambles to this Ordinance are hereby made a part of same and this Ordinance shall take effect and be in force from and after its passage."

The said motion was partially heard by Judge Landis. When Judge Landis resigned and ceased to be one of the judges of the District Court of the United States for the Northern District of Illinois, Eastern Division, no order had been entered upon said motion, no decree had been entered

by him and no order or memorandum signed by him stating his findings and conclusions existed.

Order consolidating causes.

The case was thereafter submitted to the Honorable George A. Carpenter, one of the judges of said court, and after hearing argument of counsel on said motion, and in said case, on June 18, 1923, Judge Carpenter entered an order consolidating the cause known as the Calumet suit instituted March 23, 1908, with the Main Channel suit instituted October 6, 1913. At the same time Judge Carpenter rendered his decision in said cause and entered certain other orders hereafter mentioned.

Opinion of Judge Carpenter (Vol. VIII, pp. 127-130).

"CARPENTER, District Judge (orally): It is needless to say that this litigation is of vital interest to the people of the State of Illinois. It was started nearly fifteen years ago by bill filed in behalf of the United States of America against the Sanitary District of Chicago to restrain the defendant from diverting from the waters of Lake Michigan in excess of approximately 4,500 feet per second.

The parties used the better part of six years in putting in the proof. The matter was then presented with appropriate briefs to my distinguished colleague, Judge Landis, for final determination. Judge Landis kept the matter under advisement for another six years, moved undoubtedly by the thought that the State of Illinois was being benefitted all of the time by the withdrawal of 10,000 cubic feet a second by the defendant, and that the Government was not in any way actually harmed.

On June 19th, 1920, Judge Landis rendered an oral opinion, finding in effect that the withdrawal in excess of 4,167 cubic feet a second by the Sanitary District of Chicago was without authority of law; that the withdrawals then being made reduced the level of Lake Michigan, and other of the navigable waters of the United States, to such an extent as to be an interference with navigation; that the Secretary of War, acting under Congressional powers, had never given his consent to such excessive withdrawals; that the diversion by the Sanitary District was therefore unlawful, and an injunction should issue.

A motion was made thereafter not for a reconsideration of the findings of the Court, but for the purpose of settling the terms of the final decree.

Attorneys for the Sanitary District urged the evidence showed clearly that by the construction of weirs and other compensating works at a relatively small expense, the Government could restore the various water levels which had been reduced by the flow into the drainage canal. They also urged that the State of Illinois, by appropriate legislation, had authorized the Sanitary District to agree with the United States Government to stand the cost of such weirs and compensating works and their annual maintenance, and strenuously urged upon the Court that as a condition to the entry of any injunction, the plaintiff Government should agree to erect and maintain such works at the expense of the defendant.

Counsel for the Drainage District have also urged upon the Court at this time to reconsider entirely the case upon the evidence presented.

This Court is very much disinclined to interfere with the judgment of Judge Landis. At least it is entitled to the weight that would be given to the report of a Master in Chancery or Special Commissioner. In addition, this Court has gone over the entire record, and is able to say that it agrees with Judge Landis in every respect, although from a legal standpoint, with some reluctance.

It is not necessary to go into the duties of the Secretary of War with respect to navigable waters. It is not necessary to discuss the question of whether when the State of Illinois entered the Union in 1818 it joined with special reservations with respect to its own police powers. A reading of the Federal decisions from *Gibbons* v. *Ogden*, 9 Wheat, 1, down to the present date leaves no escape from the thought that the States in adopting the Constitution surrendered to the central government everything, without stint or reservation, so far as the terms of the Constitution are concerned. The right to regulate commerce was conferred with many other things, and that right imposed upon the central government to see to it that navigation was not interfered with, either by individuals, the several States, or any foreign power. It is very true that it is the duty of the State of Illinois, in the exercise of its police power, to provide for the safety and welfare of its own people. On the other hand, if that safety and welfare depends upon the operation of the things granted to the central government, the State of Illinois must look to Congress for eventual aid or relief.

The evidence shows, and Judge Landis found and I find that the waters of Lake Michigan and other navigable waters of the Great Lakes have been reduced in level by the amount of water in excess of 4,167 cubic feet per second withdrawn from Lake Michigan by the defendant. From the standpoint of the practical mariner the testimony may not be satisfactory. It was given by engineers more or less highly technical, but thoroughly equipped in their profession. In fact no Lake captain testified that by reason of the lowering of the level of Lake Michigan was navigation interfered with. I have grave doubts whether any boat has been stranded or delayed by reason of the action of the Sanitary District.

On the other hand, the water levels have been reduced, and the Secretary of War, in whom is reposed the sole authority in matters of this kind, has determined that there was an interference with navigation, and a permit to the Sanitary District to continue in its present withdrawals was refused.

The jurisdiction of the Court has not and could not be challenged, and an injunction must issue against the defendant.

The record shows that the Sanitary District of Chicago has expended in its work some hundreds of millions of dollars; and the evidence shows rather conclusively that no other system of disposing of the sewerage in the great district covered would work so well as that devised by the Sanitary District. The City of Chicago, since the Drainage District began to operate, has practcially doubled in population. The district served by the Sanitary District holds more people than over forty states in the Union. The rate of typhoid fever since the completion of the Drainage Canal has been reduced from seventy-five per hundred thousand to a negligible number.

The testimony of Government engineers shows that it would take from ten to twenty-five years for the Drainage District to erect sewerage treatment and disposal works to handle the sewerage within the Drainage District, if the flow of water was reduced from 10,000 to 4,167 cubic feet per second.

This matter is a subject which needs the consideration of thinking people, not only in the State of Illinois, but in the whole United States. The treaty with Canada entered into some years ago seemed to contemplate an acquiescence on the part of the Canadian Government to the withdrawal of 10,000 cubic feet a second by the Drainage District. However that may be, the Secretary of War

has not given his official consent. Whether the increased withdrawal should or should not be made is properly a political and not a legal question, in the absence of consent by the Secretary of War. The Legislature of the State of Illinois, the various civic bodies, the Association of Commerce, and senators and representatives should see to it that at the earliest possible moment the situation here is brought to the attention of Congress, so that by appropriate legislation the health and welfare of this great community may be safeguarded. I have no doubt that when the matter is properly presented it will be taken up by Congress and by the State Department, and some plan devised which will bring about adequate and desired results.

It goes without saying that this Court will not issue an injunction to be effective forthwith. It cannot impose the conditions so strenuously urged by the attorneys for the Sanitary District. It is doubtful whether the State of Illinois could authorize expenditures to be made in foreign states and foreign countries to restore the water levels.

On the testimony of the Government engineers the Court might in the exercise of a sound discretion, delay the affectiveness of its injunction for from fifteen to twenty-five years to enable the Sanitary District or the State of Illinois to arrange for other means of disposal of the sewerage now handled by the Sanitary District.

Believing as I do that it is a matter for the immediate action of Congress, a decree may be prepared finding the facts as stated in the Bill and enjoining the defendant from withdrawing from Lake Michigan in excess of 4,167 cubic feet a second; the decree, however, not to go into effect for six months.

The matter must necessarily go to the Supreme Court of the United States for final settlement, and no doubt, if need be, when the record is there filed, application may be made to that Court for a *supersedeas* or further stay.

Order refusing offer of sanitary district to construct certain works—entered June 18, 1923.

(Vol. VIII, p. 130)

This cause came on to be further heard at this term and was argued by counsel, and thereupon, upon consideration thereof, it was ordered, adjudged and decreed, as follows:

(1) The motion presented herein on the 12th day of July, 1920, by the defendant, asking that the defendant be not enjoined or restrained from withdrawing from Lake Michigan less than ten thousand (10,000) cubic seconds feet of water, and in connection with which said motion an offer was made to pay cost of constructing and maintaining such works as might be provided by complainant to off-set for the lowering of the surface elevations of Lakes Michigan, Huron, St. Claire, Erie and Ontario, due to a diversion of said amount by the defendant at Chicago, is hereby denied, and the said offer is refused.

Enter. CARPENTER, JUDGE, June 18, A. D. 1923.

Decree for injunctions.
(Vol. VIII, p. 131)

This cause came on to be further heard at this term, and was argued by counsel; and thereupon, upon consideration thereof, it was ordered, adjudged and decreed as follows, viz:

That the defendant, the Sanitary District of Chicago, its Board of Trustees, officers, agents, attorneys, representatives, employees and servants, and all other persons acting or claiming or assuming to act under its authority, be, and they hereby are, and each of them hereby is, enjoined from diverting or abstracting any waters from Lake Michigan over and above or in excess of 250,000 cubic feet per minute.

The operation of this injunction is hereby stayed for a period of six months to enable the defendant to present the record herein to the Supreme Court of the United States.

Enter:

Carpenter, Judge. June 18th, A. D. 1923.

Petition for appeal allowed and injunction suspended pending appeal.

June 29, 1923, petition for appeal to the Supreme Court of the United States was filed by the defendant, together with assignment of errors. On the same day, June 29, 1923, an order was entered allowing the appeal, suspending the opera-

tion of the injunction during the pendency of the appeal upon the defendant's filing injunction bond in the sum of $5,000 on said date filed and approved. An order was further entered on said day directing that the evidence as contained in the printed record be incorporated in the transcript of record on the appeal of said cause. On the said June 29, 1923, order was entered that the printed volumes of the record of the testimony and evidence presented before the Commissioner as identified by the signature of the clerk of the court on the initial page of each volume, should be substituted as part of the record showing the testimony and evidence in place of the typewritten transcript of said testimony and evidence filed by said Commissioner. An order was entered also extending the time in which to file transcript of the record in the Supreme Court until and including the 20th day of September, A. D. 1923.

Said orders entered on June 18 and 29, 1923, appear in the record, Vol. VIII, pp. 127, 130, 131, 145 and 147.

Assignment of errors filed June 29, 1923 (Vol. VIII, p. 132.)

(In stating here the assignment of errors, we have grouped various assignments as they appear in the record, as indicated.)

The Sanitary District of Chicago alleges that the injunction entered June 18, 1923, was erroneous because:

(*a*) Plaintiff is not entitled to the injunction granted, and plaintiff's bill should have been dismissed for want of equity. (Ass. 1.)

(*b*) Under the commerce clause of the Constitution, Article 1, Section 8, Clause 3, neither Congress nor any officer of the United States has power to regulate or limit the State of Illinois or The Sanitary District of Chicago in diverting water from Lake Michigan for public welfare in the exercise of the state's police power. (Ass. 2.)

(*c*) The Act of the General Assembly of Illinois of May 29, 1889, under which The Sanitary District was organized, expressly directs defendant to divert and abstract 20,000 cubic

feet of water per minute for each 100,000 population of the district, such population being approximately 3,000,000 people. (Ass. 3, 4, 5, 6, 7.)

(*d*) Said Act of May 29, 1889, of the General Assembly of Illinois, was passed for the sole and only purpose of preserving health and protecting life under the state's police power, and neither Congress nor any officer of the United States can interfere with the reasonable exercise of such police power. (Ass. 8.)

(*e*) The Act of May 29, 1889, of the General Assembly of Illinois and the construction and operation of the works provided to be built thereunder, cannot be interfered with by the United States, when the primary and sole purpose of such legislation and operation of said works is for public health and welfare of the people of the state and the impairment of navigation, if any, is only the indirect result of the operation of said Act of the General Assembly of Illinois and the works constructed thereunder. (Ass. 9.)

(*f*) The pure, wholesome, potable drinking water supply for the people of Chicago, its environs and those within the territorial limits of the defendant, the disposal of the sewage of said people, and the diversion of same from the water supply, can only be obtained through the operation and maintenance of defendant's diversion works constructed under said Act of the General Assembly of Illinois of May 29, 1889, requiring a diversion of 20,000 cubic feet of water per minute for each 100,000 of population (population now upwards of 3,000,000 people.) (Ass. 10, 11, 12, 13 and 14)

(*g*) With the diversion limited to 250,000 cubic feet of water per second, as required by said injunction, works to artificially dispose of sewage supplementary to said diversion and works to filter the water supply of the people, cannot be constructed within a period of less than twenty years, by reason of the inability of the Sanitary District, defendant, to raise funds therefor by taxation and by the issuance of bonds. (Ass. 15, 16, and 17)

(*h*) The Act of Congress of March 2, 1827, entitled "An Act to grant a quantity of land to the State of Illinois for the purpose of aiding in opening a canal to connect the waters of the Illinois River with those of Lake Michigan", authorized the State of Illinois to build the main channel of the defendant, Sanitary District, supplementary to or in place of the old Illinois Michigan Canal constructed in 1848, and to divert from Lake Michigan for said main channel at least 600,000 cubic seconds feet of water per minute and in excess of 250,000 cubic feet per minute fixed by said injunctional order. (Ass. 18, 19, 20, 21 and 22)

(*i*) The United States had full and complete knowledge of the passage of the Act of May 29, 1889, providing for the construction of the main channel of the Sanitary District with its attendant diversion, the progress of construction, completion, and the purpose of such works and invited and acquiesced in said diversion provided by said Act of May 29, 1889, and is estopped to interfere with it. (Ass. 23)

(*j*) Congress has by various acts fixed the project depths of all harbors and connecting waters of Lake Superior, Michigan, Huron, Erie and Ontario, and the actual depths of water in such harbors and connecting waters has not been less than the project depths fixed, nothwithstanding defendant's diversion. (Ass. 24 and 25)

(*k*) The cost and financial burden resulting to the defendant by virtue of the said injunction and the limitation of said diversion is great, amounting to upwards of $250,000, and the damage to plaintiff by reason of the alleged injury to navigation is slight, and all claimed damage to navigation may be offset or compensated for by construction of compensating works, which cost would not exceed $475,000. (Ass. 26-28)

(*l*) The offer of defendant to pay the cost of constructing and maintaining compensating works to offset for the alleged lowering of the surface elevation of the Great Lakes system, on condition that the decree to be entered should

only enjoin defendant from diverting in excess of 10,000 cubic feet of water from Lake Michigan, should have been accepted by the court and a decree entered as requested by the defendant upon the condition that defendant comply with such offer. (Ass. 29-30)

(*m*) Congress has by various acts appropriated money for and required surveys and reports for a waterway from Chicago to the Gulf of Mexico, whereby the diversion of water by the defendant to the amount of 600,000 cubic feet per minute would be utilized and has by various acts also required surveys as to the means of offsetting or compensating for the lowering of the surface elevations of the Great Lakes system by said diversion, and has thereby indicated that it treated the said diversion by the defendant as existing, and did not intend to disturb it. (Ass. 31-32)

(*n*) Act of Congress of June 29, 1906, relating to the diversion of water from the Niagara River, known as the Act for the Preservation of Niagara Falls, expressly prohibits interference with diversions from the Great Lakes for sanitary or domestic purposes except as Congress might in the future provide. (Ass. 33)

(*o*) The works of the Sanitary District were commenced prior to the passage of the Rivers and Harbors Act of September 19, 1890, and such works are recognized by said act as authorized by law. (Ass. 34)

(*p*) Sections 9 and 10 of the Rivers and Harbors Act of March 3, 1899, do not authorize the Chief of Engineers or the Secretary of War in any manner to supervise or regulate or control the diversion of water by the defendant. (Ass. 35-36-37)

(*q*) Permit of May 8, 1899, authorized the Sanitary District to open its main channel and was without limitation as to amount except the capacity of the main channel of the Sanitary District as fixed by law. This permit was subject to a condition only as to limitation of flow—that if the cur-

rent should be unreasonably obstructive to navigation in the Chicago River, the Secretary of War might modify the discharge from Lake Michigan through the river. Thereafter, due to the then shallowness and narrowness of the Chicago River, its South Branch and West Fork, the Secretary of War ordered the flow limited to 250,000 cubic feet per minute. Because of such limitation for the purpose of providing for the greater flow of 10,000 cubic seconds feet, the Sanitary District, with the consent and approval of the Secretary of War, widened and deepened the channels of said rivers at a cost of approximately $13,000,000 so that there could be withdrawn through said river channels the amount of water required by said Act of May 29, 1889, without injury to navigation. Thereafter the Secretary of War or other officer of the United States was without authority to enforce the order limiting the withdrawal to 250,000 cubic feet per minute, made because of the then narrowness and shallowness of the channels of said rivers. (Ass. 38-39-40-41)

(*r*) The abstraction and withdrawal of water from Lake Michigan by defendant to the amount of 600,000 cubic feet of water per minute, or 10,000 per second, has not and will not impair the navigable capacity of any of the navigable waters of the United States, has not been observed by any lay witnesses, navigator or captain of any ship, or any one engaged in navigation. Such claim is only the result of the analyses of expert witnesses. (Ass. 41-42-43-44-45-46-47-48-49)

(*s*) Defendant cannot observe the injunctional decree without causing pollution of the water supply of upwards of three million people within defendant's limits, from which would result epidemics of typhoid fever and other water-born diseases. (Ass. 50-51.)

(*t*) Injunctional decree herein holds unconstitutional the Act of General Assembly of Illinois of May 29, 1889, under which the Sanitary District, the defendant, was organized. (Ass. 52)

(*u*) Treaty between the United States and Great Britain of January 11, 1909, concerning Canadian boundary waters, recognizes the diversion by the defendant to the amount of 10,000 cubic feet of water per second and precludes an injunction herein as to any diversion of 10,000 cubic feet seconds or less. (Ass. 53-54-55)

(*v*) It does not appear from the evidence that the diversion proposed by the defendant pursuant to said Act of May 29, 1889, under all the facts and circumstances, has obstructed or would unreasonably obstruct navigation. (Ass. 56-57 and 60)

(*w*) Decree herein enforces an arbitrary and unreasonable course pursued by the Secretary of War and the Attorney General. (Ass. 58)

(*x*) The Court should have balanced the equities and in so doing should have refused the injunction and dismissed the complainant's bill for want of equity. (Ass. 59)

(*y*) Congress will not be deemed to have acted concerning a matter of local regulation such as is embraced in the Act of the General Assembly of May 29, 1889, providing for defendant's diversion works, unless it has passed some special law with reference to the alleged obstruction. (Ass. 61)

EVIDENCE.

The exhibits attached to and made a part of both the bill of complaint in the Calumet suit and the complaint in the main channel suit, and in the answers thereto by the defendant, and documents quoted in the pleadings, were either admitted by the pleadings or introduced in evidence.

The United States will be hereinafter designated "Plaintiff."

The evidence of plaintiff in chief related principally to establishing the increment of the Rivers St. Clair, Niagara and St. Lawrence by witnesses who were or had been connected with the United States Lake Survey. The increment of a river is the increase or decrease in its flow due to the rise or fall of one foot of the river's controlling lake. The Lake Survey had, running over a period of years beginning with the year 1898, made a great number of discharge measurements of these rivers. Hourly records had been kept of the stage of the various lakes during this period by automatic recording gages. The discharge measurements were then plotted on a piece of paper, each one placed according to the lake stage at the particular time the measurement was made. One side of such paper was measured showing discharge in cubic seconds feet. Another side of such paper vertical to the other was measured showing lake stage in feet above sea level. Thus a point could be ascertained on the paper which would indicate a particular discharge measurement and the elevation of the lake at the time the discharge was made. Having plotted all the discharge measurements in this way, a line was drawn through the plottings which represented the mean of such plottings. The line having been drawn, the discharge of the lake at any elevation within the range of the discharge measurements could be ascertained and thus the difference in the discharge measurement at elevation one foot above any

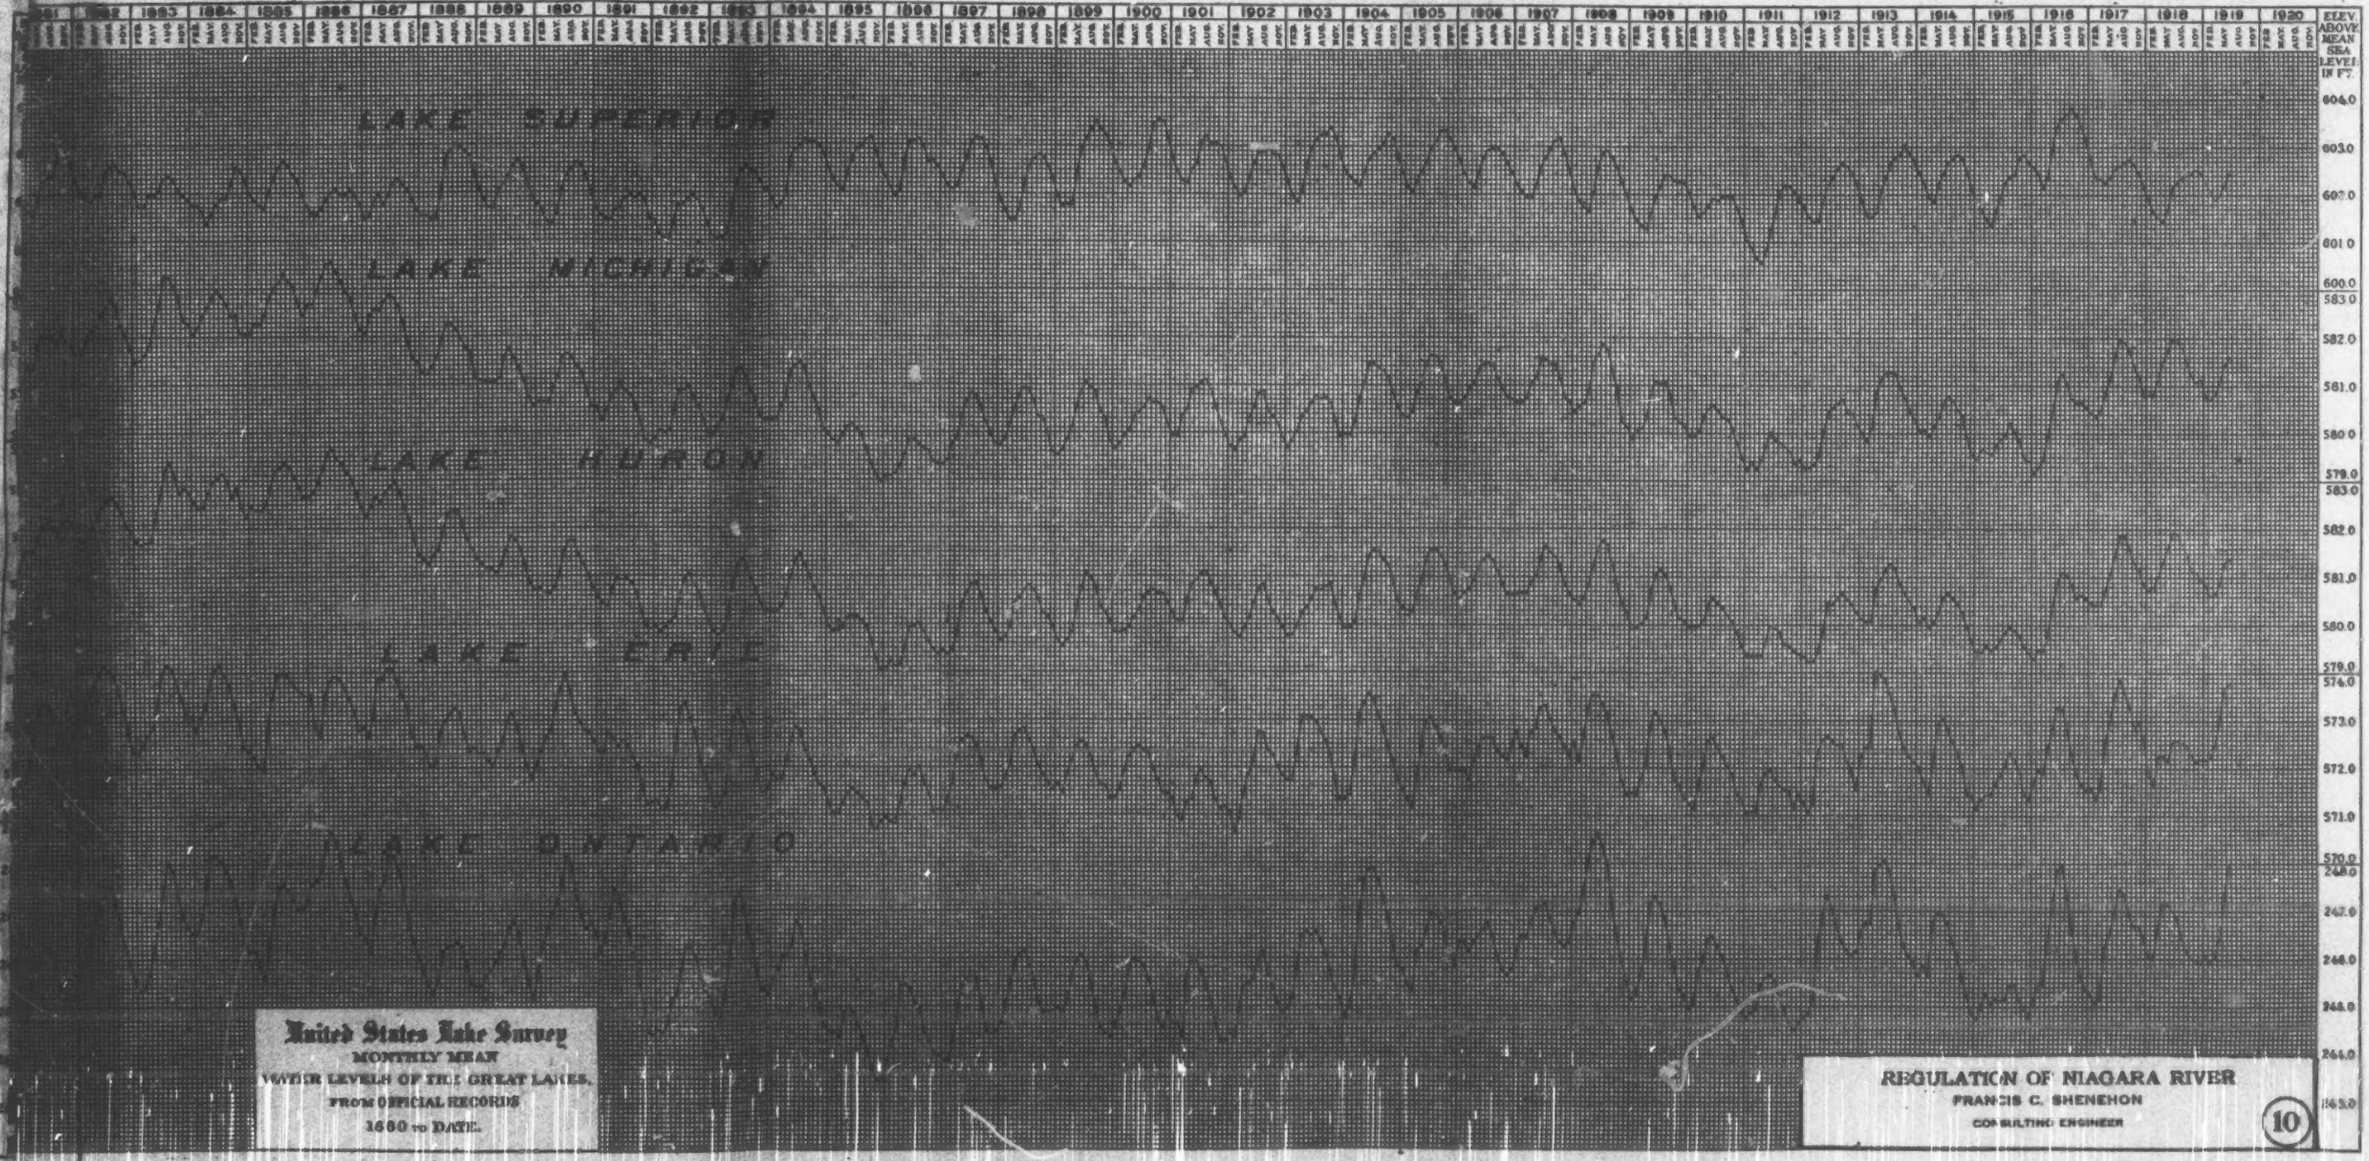
Complainants Exhibit 5.



elevation taken or one foot lower than any elevation taken, could be ascertained by the simple method of subtraction.

Thus, in this way, an increment was determined. Having obtained the increment, it was estimated that a withdrawal or diversion of water through the additional outlet constructed by the Sanitary District would permanently lower the surface elevation of the controlling lake the fraction of a foot, represented by the amount of such diversion, divided by the ascertained increment. It was also estimated that approximately nine-tenths of the full effect of any given amount of diversion through the additional outlet would take place in about four to five years after the diversion commenced.

Complainant's Exhibits 1 to 4, inclusive, show the plottings of the measurements and the increments derived for the various rivers involved, and Complainant's Exhibit 5 is Lake Survey Hydrograph of the Great Lakes showing surface elevations of the lakes, from 1860 to end of the year 1912. They appear opposite this page (Rec., Vol. VII, pp. 49 to 57, inclusive.)

Other witnesses were produced by the plaintiff to show that there were certain large boats navigating the Great Lakes and their connecting channels, operating principally between Lake Superior ports and those of Lake Erie, which could load to depths greater than the depths provided at critical points of navigation on the Great Lakes, such as Sault Ste. Marie, St. Clair River, Lake St. Clair, Detroit River and certain harbors of Lake Erie; that the inability to load these large boats to the full capacity, would decrease the amount that they could carry on each trip by from 90 to 100 tons for each inch of loss of draft; that there were a great number of such boats (over 100); that they make a certain number of trips each season (approximately twenty-five each), and therefore there was a material injury to navigation by this diversion.

Defendant's evidence, in response to the line of evidence above mentioned, related principally to showing:

First, that the discharge measurements of the different rivers were inaccurate, and the correct increment was not obtained, and therefore the effect upon the different controlling lakes was not as great as estimated by the plaintiff's witnesses by about two inches.

Second, that due to the hourly and daily continuous fluctuations and oscillations of the lake surfaces, boats could not load within such narrow limits, and therefore the loss of carrying capacity due to the few inches (five inches on Lake Michigan for 10,000 seconds feet diversion), claimed effect upon the lakes by the diversion, was negligible;

Third, that the cost of dredging the critical points of navigation to offset for the claimed effect upon navigation, would be small;

Fourth, that compensating or regulating works restricting the flowage capacity of the different rivers mentioned, could be, at small expense, installed, and their operation would entirely restore the lake levels to their natural condition without injury to navigation, and that such method had been recommended by various boards of engineers of the United States, made pursuant to Congressional acts.

Hydraulic Expert Evidence.

The evidence of the plaintiff and defendant upon the ascertainment of the correct increments of the different rivers involved and upon the effect of different amounts of diversion upon the levels of the different lakes will be stated briefly. Such evidence consists of the testimony of hydraulic engineering experts on both sides covering a large portion of the record. Only enough of the testimony of the experts on both sides will be stated to show the methods used and results reached.

The hydraulic engineering experts for the plaintiff in its evidence in chief, and their respective qualifications, are as follows:

ALFRED NOBLE (Vol. I, pp. 1-30):

Graduate civil engineering, University of Michigan; later honored with the degree of LL. D.; for twelve years at Sault Ste. Marie in the employ of the United States, and had local charge of the St. Mary's Falls Canal and River; a member of the Board of Engineers on Deep Waterways, which worked out projects for thirty foot channels connecting the Great Lakes with the Atlantic by way of the Hudson River; member of Nicaragua Canal Board and the Isthmian Canal Commission; president of the American Society of Civil Engineers; while member of the Board of Engineers on Deep Waterways, caused measurements of the discharge of the Niagara River to be made in 1897 and 1898.

EUGENE E. HASKELL (Vol. I, pp. 30-49):

Graduate of the College of Civil Engineering, Cornell University, and when he testified, he was dean or director of said college; was then a member of the International Waterways Commission; had been connected with river and stream hydraulics for approximately thirty years; studied ocean currents, including the Gulf Stream, under the Coast and Geodetic Survey; made stream measurements of the Mississippi River, and the discharge measurements of the rivers of the Great Lakes principally were under his direction as principal assistant engineer of the United States Lake Survey. Mr. Haskell designed a current meter known as the Haskel meter.

W. EDWARD WILSON (Vol. I, pp. 49-57):

Graduate College of Civil Engineering, Cornell University; had charge of the hydraulic measurements on the St. Mary's River in 1901 and 1902, and did some similar work on the Niagara River in 1903; while assistant professor of civil engineering in the University of Utah, for three years did some

hydraulic work in the Rocky Mountains. At the time he testified in 1909, he was secretary of the International Waterways Commission, and had been for two years and a half theretofore. He had to do with the hydraulic investigations of the Great Lakes involved in the discussion of the proposed regulation of Lake Erie, in the report of the International Waterways Commission.

GEN. O. H. ERNST (Vol. I, pp. 57-58):

Retired brigadier general of the Corps of Engineers, United States Army; graduate of West Point; from 1871 to 1878 was instructor of practical military engineering at West Point, and for eight years thereafter he was in charge at St. Louis of the River and Harbor District there, including the Mississippi River. For ten years he was a member of the Missouri River Commission, and for six years a member of the Mississippi River Commission, serving as its president from 1903 to 1906; at Galveston he was in charge of the rivers and harbors of the Texas coast; 1899 was a member of the Isthmian Canal Commission; 1901 to 1905 he was stationed at Chicago in charge of the rivers and harbors of that district, and was also engineer of the Northwest Division, which included the Great Lakes System as far east as Erie, Pennsylvania; was chairman of the Board of Engineers which made surveys and estimates for waterway from Chicago to St. Louis; in 1905 he was appointed on the International Waterways Commission as chairman of the American Section. The Commission made a special report on the Chicago Drainage Canal.

COL. CURTIS McDONALD TOWNSEND (Vol. I, pp. 71-72):

He was an officer of the Corps of Engineers; was stationed at Detroit; had charge of the District, including the Detroit and St. Clair Rivers, Lake St. Clair and certain harbors in

Lake Huron, and the St. Mary's River, including the ship locks at that place. At one time he was in charge of the Mississippi River District, the Grand Rapids District, including the rivers and harbors on the east shore of Lake Michigan, the Rock Island District, including the upper Mississippi River from St. Paul to St. Louis, and the Harbor of Manilla in the Philippines; the rivers and harbors of the Cleveland District, including the harbors of Lake Erie from Toledo to Conneaut.

EBEN S. WHEELER (Vol. I, pp. 87-155):

Graduate of civil engineering of the University of Michigan; was United States Assistant Civil Engineer in the office at Detroit; served under Colonel Townsend; engaged for a number of years on surveys of the Great Lakes made by the United States Lake Survey; assisted in some of the earlier stream measurements in the Detroit and St. Clair Rivers; was at Sault Ste. Marie, succeeding Alfred Noble there, in charge of the operation of the ship locks and in the improvements of the river channels; was chief engineer of the Nicaragua Commission of 1898 and 1899.

LOUIS C. SABIN (Vol. I, p. 156):

Graduate of the University of Michigan in civil engineering, and assistant on the improvements of the St. Mary's River from 1890 to 1897; made surveys and discharge measurements for the Lake Survey from 1898 to 1903; assisted on St. Mary's River improvements 1903 to 1905; 1905 and 1906 secretary of the American Section of the International Waterways Commission. At the time he testified, was in local charge of improvements on the St. Mary's River, and general superintendent of St. Mary's Falls Canal; 1898 to 1906 Mr. Sabin was in immediate charge of the hydraulic work on the St. Clair River, and in the reduction of the observations made.

MAJOR CHARLES KELLER (Vol. I, p. 224):

Graduate of West Point; since 1893 has been engaged in the work of river and harbor improvement; the United States Lake Survey which made the hydraulic measurements involved in this case, was under his charge from May, 1907, to the date he testified in 1909; had given special duty to lake levels as connected with the discharges of the connecting rivers.

SHERMAN MOORE (Vol. I, p, 252):

Graduate of the University of Wisconsin as a civil engineer; employed by the United States Lake Survey and has been engaged in such work since 1902 to the date he testified in 1909; for three years preceding 1909, he was almost exclusively employed on hydraulic measurements on the Niagara River on work connected with the investigation and preservation of Niagara Falls.

F. G. RAY (Vol. I, p. 273):

Graduate of the University of Iowa, 1902, and engaged in civil engineering work since that time; with the Mississippi River Commission until 1900; since then has been employed by the United States Lake Survey; charge of the field parties on triangulation, hydrography and topography during summer seasons and in winter in the reduction of the notes of water levels, hydraulics, etc.

F. C. SHENEHON (Vol. I, pp. 283-427).

Graduate of University of Minnesota; at the time of his direct testimony in 1909, he was principal civilian engineer of the United States Lake Survey; between 1886 and 1888

his engineering work consisted principally in the location and construction of railroads; from 1888 to 1891, in general practice as a civil engineer at Sault Ste. Marie, and then entered the service of the engineering department of the United States in the construction of the Poe Lock at Sault Ste. Marie; there until 1898; his work included channelizing the St. Mary's River, making discharge measurements of the St. Mary's River; in 1898 he was engineer for the Board of Engineers on Deep Waterways in charge of the Buffalo office. This work included slope measurements on rivers and the overseeing of discharge measurements at the International Bridge Section. He then took up work as an engineer for the United States Lake Survey, and between September, 1898, and August, 1900, made extensive measurements of the flow of the Niagara River and investigations of its hydraulics. In 1900 he took up the hydraulic measurements of the St. Lawrence River and was engaged in this work during the fall of 1900 and the spring of 1901. In the winter of 1901 additional measurements of the flow of the St. Lawrence was made through the ice; made report on preservation of Niagara Falls; succeeded E. E. Haskell as principal assistant engineer of the Lake Survey. In 1906 to 1909 he had jurisdiction over the hydraulic work done on the St. Clair and Niagara Rivers. In 1909 resigned and became Dean of the College of Engineering of the University of Minnesota.

Williams Exhibits 1 to 15, inclusive, are Lake Survey Charts or Maps, showing the five Great Lakes and their connecting channels, ~~and appear as appendices to this narrative.~~ (Rec., Vol. VII, pp. 59 to 87, inclusive.)

The witnesses for the plaintiff above mentioned in their direct testimony stated and concluded as follows:

(A.) That a diversion of 23,820 cubic feet per second from Lake Michigan would lower the level of the said Lake and Lake Huron, one foot. (Noble, Vol. I, p. 8; Sabin, Vol. I, p. 165; Keller, Vol. I, p. 228; Moore, Vol. I, p. 264; Shenehon, Vol. I, p. 296.)

That a diversion of 21,900 or 21,640 cubic feet per second from Lake Erie would lower the level of the lake one foot. (Noble, Vol. I, p. 13; Wheeler, Vol. I, p. 113; Moore, Vol. I, p. 265; Shenehon, Vol. I, p. 302).

That a diversion of 28,870 cubic feet per second from Lake Ontario would lower the level of that lake one foot. (Noble, Vol. I, p. 12; Wheeler, Vol. I, p. 113; Sabin, Vol. I, p. 172; Moore, Vol. I, p. 257.)

That any other amounts of diversion would lower the level of each lake in proportion to the respective amounts for one foot lowering. (Noble, Vol. I, p. 9; Haskell, Vol. I, p. 40; Wilson, Vol. I, p. 52; Ernst, Vol. I, p. 60; Wheeler, Vol. I, p. 99; Sabin, Vol. I, p. 172; Keller, Vol. I, p. 229; Moore, Vol. I, p. 266 and Shenehon Vol. I, p. 296.)

It was further developed that the determination of the above items were based upon measurements of the St. Clair, Detroit, Niagara and St. Lawrence Rivers by means of Haskell current meters. (Haskell, Vol. I, pp. 32, 36; Keller, Vol. I, p. 226; Moore, Vol. I, p. 260.) Also that the discharge so measured was assumed to be that due and corresponding to the elevation of the respective lakes at approximately the same time as the discharge measurements. (Shenehon, Vol. I, p. 300.)

(B) That the construction of the Gut Dam on the St. Lawrence River has decreased the flow of the St. Lawrence River about five and one-half per cent, (Moore, Vol. I, p. 256; Shenehon, Vol. I, p. 295), and has raised the level of Lake Ontario about five inches. (Shenehon, Vol. I, p. 308.)

That there have been no changes in the channels of the St. Clair and Detroit Rivers affecting the levels of the Lakes during the period of the government improvements therein. (Sabin, Vol. I, p. 175; Keller, Vol. I, p. 241; Shenehon, Vol. I, p. 317.)

As to the points mentioned, on cross examination, the witnesses testified:

As to "A"—That it had been assumed that the position of Lake St. Clair need not be considered in establishing the condition of lowering of Lakes Michigan-Huron from the experiments (Shenehon, Vol. I, p. 368), and that a series of measurements in 1901 had been excluded from the computation because Lake St. Clair was abnormally low. (Shenehon, Vol. I, p. 367.)

As to "B"—That the improvements in the St. Mary's River had certainly lowered the level of the water at the locks at Sault Ste. Marie (Shenehon, Vol. I, p. 327), and that it was possible that the improvements in the St. Clair and Detroit Rivers might have lowered the levels of Lakes Michigan and the St. Clair by small amounts. (Shenehon, Vol. I, p. 374.)

The lowerings in inches for 10,000 cubic seconds feet diversion at Chicago for the different lakes, as testified to by the plaintiff's different witnesses in chief, are shown by the following table:

Ref. No.	Witness	Michigan and Huron	Ref. Record	Erie	Ref. Record	Ontario	Ref. Record	
1	Keller			5.7	I-237-8			Quintus
2	Keller	5.	I-229	5.5	I-234	4.2	I-233	1893

11	Shenehon	6.2	I-296	5.5	I-304	4.3	I-295	

The hydraulic expert witnesses and their respective qualifications, testifying for the defendant in chief are as follows:

GARDNER S. WILLIAMS (Vol. II, pp. 566-990):

Ann Arbor, Michigan; member of the American Society of Civil Engineers, Detroit Engineering Society, American Water Works Association, New England Water Works Association and others; received the degree of Bachelor of Science in Civil Engineering University of Michigan, 1889; interested in and connected with the study of hydraulics and hydrography of the Great Lakes from the time he became civil engineer of the Board of Water Commissioners of Detroit in 1893; in 1898 became Prof. of experimental hydraulics and engineer in charge of the Hydraulic Laboratory, Cornell University; there until 1904, when he became Prof. of Civil, Hydraulic and Sanitary Engineering, at University of Michigan; in 1911 resigned to enter consulting practice; consulting engineer for the Michigan-Lake Superior Power Company on hydraulic installation at Sault Ste. Marie, and upon discharge measurements of the St. Mary's River before that. 1899-1900 consulting engineer for the Edison Sault Electric Company and the Chandler-Dunbar Water Power Company, and as such designed and supervised the construction of power plant in rapids at Sault Ste. Marie; consulting engineer for the Eastern Michigan Edison Company on water power developments on the Huron River; consulting engineer to Canadian Light & Power Company in connection with power development and incidental improvements to navigation on the Couteau and Cedar Rapids of the St. Lawrence River near Montreal.

FREDERICK P. STEARNS (Vol. II, pp. 990-1143):

Boston, Massachusetts; consulting civil engineer; been engaged in such work since 1869; from 1872 to 1880 was engaged upon the construction and operation of a new system

of water supply for Boston; 1887 measured the flow of the Sudbury River, using the current meter; made experiments upon the flow of water over weirs through channels and pipes and upon the current meter, the results of which were published in the transactions of the American Society of Civil Engineers; 1880-1886 engaged in the construction and later in the operation of the Boston Main Drainage Works and sewage disposal for the city; 1886-1895 chief engineer of the Massachusetts Board of Health. This work involved the discharge of sewage into streams and the care and control of streams used for water supply and the study of the condition of polluted rivers; 1895-1907 chief engineer of the Metropolitan Water Board and its successor, the Metropolitan Water & Sewer Board; was consulted in many cases, such as reporting upon the sewerage of the District of Columbia, consulting engineer of the First Rapid Transit Commission of Boston; consulting engineer to the Charles River Basin Commission of Boston; consulting engineer of the Board of Water Supply of the City of New York; 1905 to 1906 member of the International Board of Consulting Engineers for the Panama Canal; one of the advisory engineers to the Sewage Commission of the City of Baltimore; November and December, 1906, was a member of Board of Consulting Engineers to examine and report upon means for supplying water to the City of Los Angeles; 1905 received honorary degree of Master of Arts from Harvard University; 1906 Doctor of Science from the University of Michigan.

JOHN R. FREEMAN (Vol. III, pp. 1145-1195):

Providence, Rhode Island; civil engineer and engaged in such practice since 1876; graduated at that time in civil engineering, Massachusetts Institute of Technology; from 1876 to 1886 was principal assistant engineer of the Water Power Company controlling the Merrimac River at Lawrence, Massachusetts. A large part of his duties was measuring the quantity of water used by various factories and the flow of

the Merrimac River. At that time also was principal assistant to Hiram F. Mills in consulting engineering; measured the water used by factories at Manchester, New Hampshire; made investigations for water power development at Concord, New Hampshire, involving the flow of the river and making gagings of it; made exhaustive studies of the methods of accurate measurement of flowing water; the yield of water sheds of rivers and studies of evaporation. In 1895 member of Metropolitan Water Board of Massachusetts, which was to build waterworks to supply about fifteen different municipalities, Boston being one. For two years consulting engineer, New York State Water Supply Commission. For twelve years was consulting engineer to the City of New York in connection with the improvement and enlargement of its water supply, involving the estimation of the yield of many watersheds, etc.; consulting engineer to many cities in connection with water supply—namely, Nashua, New Hampshire, Los Angeles, California, Baltimore, San Francisco, Mexican Government on extension of water supply of the City of Mexico; consulting engineer of the Canadian Government on matters of water power development on various rivers in Western Canada; made studies of obstructions to flow of rivers caused by ice, such as the St. Lawrence River at Massena and at the Long Soo Water Power Development on said river; consulting engineer to Water Power Companies, Niagara Falls; consulting engineer to Mississippi Water Power Company with reference to the development of water on Mississippi River at Keokuk, Iowa; member of two boards of engineers appointed by President to investigate matters connected with the building of the Panama Canal; planned water power development of the Great Western Power Company upon the Feather River in California.

JOSEPH RIPLEY (Vol. III, pp. 1277-1353):

Resides Albany, New York; civil engineer; 1867 graduated civil engineering, University of Michigan; 1913 at the time he testified, he was consulting engineer to the state engineer on the Barge Canal Construction; member American Society of Civil Engineers; Western Society and others; 1877 employed by the Government on canal work at Sault Ste. Marie, Michigan; construction of the Weitzel Ship Lock, Alfred Noble being the civilian engineer in charge; was so connected with the work on the Great Lakes until 1906; first two years construction of the Weitzel Lock; next survey work of the St. Mary's River; 1879 dredging for deepening the channels of that river; 1897 became general superintendent in charge of the ship canal at Sault Ste. Marie and the St. Mary's River; was familiar also with the improvement of navigation on the Detroit River; was a member of the Board of Consulting Engineers in August, 1905, which studied and reported as to the type of canal to be built at Panama; was principal assistant engineer in charge of the plans for the construction of locks and regulating works in connection with the Panama Canal.

E. W. SCHROEDER (Vol. III, pp. 1533-1563):

Resides Ithaca, New York; graduate of University of Washington (Seattle), 1900; pursued post-graduate work at Cornell in engineering; at the time he testified, 1913, teacher and engineer at Cornell University and in charge of the hydraulic laboratory; has been connected with the university as such practically since 1900; made many experiments in hydraulics at the laboratory; made numerous experiments at the request of Gardner S. Williams in the hydraulic laboratory of Cornell University to ascertain the operation of the Haskell current meter in swift, turbulent and slow flowing waters. Such experiments were carried on in conjunction with Prof. K. B. Turner of the College of Civil Engineering, Cornell University.

KENNETH B. TURNER (Vol. III, pp. 1563-1592):

Resides at Ithaca, New York; teacher of civil engineering at Cornell University; at Cornell University for five years taking degrees of Civil Engineer and Master of Civil Engineer; with the United States Lake Survey for approximately two years, beginning with January, 1905. This was after the degree was obtained at Cornell. While with the Lake Survey worked in connection with river discharge measurements at Sault Ste. Marie and the St. Mary's River; also reduced the discharge measurements; used the Haskell current meter; carried on experiments with Professor Schroeder, Cornell University Hydraulic Laboratory, to ascertain the operation of the Haskell current meter in turbulent, swift and slow moving waters.

LYMAN E. COOLEY (Vol. III, pp. 1703-1810):

Resides at Evanston, Illinois; civil engineer; when testified (1914) consulting engineer to the Sanitary District of Chicago; received the degree of civil engineer at Rensselaer Polytechnic Institute, Troy, New York, in 1874, and has practiced the profession since. First eleven years, to 1885, connected with Northwestern University at Evanston, for three and one-half years of which was professor of Engineering and Mathematics; for six years during this period was assistant engineer to the war department on improvement of western rivers; from 1884 work consisted principally with the development of the Chicago Sanitary District Works; designed intercepting sewers for the lake front; 1905-1907 member International Deep Waterways Commission; engineer for the Union Water Company, Denver, Colorado; constructed the Cheseman Dam, 210 feet high; designed the Keokuk Water Power Works; reported on the Barge Canal; consulting engineer to the Gulf Deep Waterway Association; employed by the attorney general of Illinois in the case of the State of Illinois *vs.* Economy Light & Power Company, involving the

proposed dam of that company across the Desplaines River; was later employed by the United States in its suit against the Economy Light & Power Company, involving the same dam; 1886-1887 was engineer to the Drainage & Water Supply Commission, which recommended the construction of the works afterward built by the Sanitary District of Chicago to protect the water supply of Chicago.

The Great Lakes occupy six depressions in the earth surface, and receive the drainage or run-off from a large area of adjacent land partly in Canada and partly in the United States, which run-off reaches them in major part by flowing over the surface in rivers and creeks. (Rec., Vol. II, p. 584.)

The precipitation varies in amount from month to month and year to year. On the Huron-Michigan drainage area, it varied from 38.63 inches in 1883 to 27.17 inches in 1895, a variation of about 42% from the minimum. (Rec., Vol. VII, p. 202-208.) Evaporation takes place from the lake surfaces and from the ground and plant life.

These two agencies, precipitation and evaporation, are the principal ones affecting the annual and monthly elevation of the Great Lakes, and are responsible for the major part of their fluctuations. (Rec., Vol., II, p. 585.)

The levels of the Great Lakes were actually higher during the ten years immediately following than during the ten years immediately preceding the opening of the Chicago & Sanitary Ship Canal. (Rec., Vol. II, p. 727-739.)

The diversion from the Great Lakes at Chicago through the Sanitary & Ship Canal, varied progressively from 4,300 cubic feet per second in 1900, to approximately 7,600 cubic feet per second in 1910, and 1913. (Rec., Vol. III, p. 1618.)

The defendant's witnesses above mentioned testified and concluded as follows:

That it would take a much larger diversion of water from Lakes Michigan-Huron than the amount testified to by the

plaintiff to lower their surfaces one foot. (Williams, Vol. II, pp. 643, 649, 657, 658, 660, 662, 663, 664 and 740; Stearns, Vol. II, pp. 1032, 1036; Freeman, Vol. III, p. 1148); that it would take a larger diversion than that testified to by the plaintiff to lower the surface of Lake Erie one foot. (Williams, Vol. II, p. 668, 670, 671, 672, 674, 722 and 740; Stearns, Vol. II, pp. 1104, 1106); that it would take a larger diversion from Lake Ontario than that testified to by the plaintiff to lower its surface one foot. (Williams, Vol. II, pp. 666, 740; Freeman, Vol. III, p. 1148.)

That the assumptions by which the measurements of discharge were rated to the lake elevations producing them were incorrect. (Williams, Vol. II, pp. 651, 652, 654; Stearns, Vol. II, p. 1032, 1035; Freeman, Vol. III, pp. 1149, 1150; Cooley, Vol. III, pp. 1772, 1784.)

That the degree of precision of the discharge observations was much less than claimed by complainant. (Williams, Vol I, p. 737; Freeman, Vol. III, pp. 1178, 1187.)

That the accuracy of measurement was not sufficiently perfect to enable the detection of a variation of flow of 10,000 cubic feet per second. (Williams, Vol. II, p. 636; Freeman, Vol. III, pp. 1150, 1186-1189); that the exclusion of the 1901 observations in the St. Clair River was in error. (Williams, Vol. II, p. 643), and that including these the amount of diversion necessary to lower the lake one foot would be increased seventeen per cent. (Williams, Vol, II, p. 639), and that the influence of Lake St. Clair could not be ignored. (Williams, Vol. II, p. 639; Stearns, Vol. II, p. 1031; Freeman, Vol. III, p. 1149.)

That the Niagara discharge was inconsistent with those of the St. Lawrence, St. Clair and Detroit Rivers, and inconsistent with the physical characteristics of the several drainage areas. (Williams, Vol. II, pp. 671-737; Stearns, Vol. II, pp. 1014, 1020-1024, 1105; Freeman, Vol. III, pp. 1178-1180.)

That the improvements for navigation in the St. Clair and Detroit Rivers had lowered the level of Lakes Michigan-

Huron and St. Clair by greater amounts than the contemplated diversion at Chicago would do, thus indicating that keeping the lake surfaces at a high level was of secondary importance from a navigation standpoint. (Williams, Vol. II, p. 705; Stearns, Vol. II, pp. 1015, 1017; Freeman, Vol. III, pp. 1166, 1172; Cooley, Vol. III, p. 1783.)

That the improvements in the Niagara River had lowered the level of Lake Erie (Cooley, Vol. III, p. 1783), and that similar work in the St. Lawrence River had lowered the level of Lake Ontario. (Williams, Cross Examination, Vol. II, p. 823; Cooley, Vol. III, p. 1783.)

That the navigation improvements now substantially completed had been planned with a view to providing for the effects of a diversion of 10,000 c. f. s. (Ripley, Vol. III, pp. 1301, 1303); and that any lowering by such diversion could be compensated for by obstructions in the channels connecting the lakes without detriment to navigation. (Freeman, Vol. III, pp. 1172-1174; Ripley, Vol. III, pp. 1311-1313; Williams, Vol. II, pp. 742-743.)

Gardner S. Williams, the principal witness for defendant, on cross examination, testified (Vol. II, pp. 747-750) that a diversion of 10,000 cubic second feet at Chicago would not affect the levels of the different lakes more than the following:

Lakes Michigan-Huron	4.1 inches
Erie	3.5 inches
Ontario	4 inches

For a diversion of 14,000 cubic seconds feet, (Vol. II, p. 742)—

Lakes Michigan-Huron	5.7 inches
Erie	4.9 inches
Ontario	5.6 inches

AVERAGE DISCHARGES OF THE VARIOUS OUTLET RIVERS OF THE GREAT LAKES.

St. Mary's River	1900-1904	76, 060 cubic feet per second. (Williams, Rec., Vol. II, p. 683.)
St. Clair River	1900-1907	197,633 cubic feet per second. (Williams, Rec., Vol. II, p. 670.)
Niagara River	1900-1907	200,072 cubic feet per second. (Williams, Rec., Vol. II, p. 670.)
St. Lawrence River	1900-1907	247,762 cubic feet per second. (Williams, Rec., Vol. II, p. 674.)

Plaintiff's rebuttal evidence on hydraulics of the Great Lakes.

The plaintiff in rebuttal produced some of the witnesses that it had presented in its evidence in chief, and some other witnesses employed by the United States Lake Survey. These rebuttal witnesses testified and concluded:

That the methods of determining the amount of diversion to produce a lowering of one foot on the several lakes by the defendant were incorrect, particularly as applied to the Niagara River. (Ray, Vol. V, pp. 2797, 2798, 2799, 2802, 2804; Moore, Vol. V. p. 2877; Shenehon, Vol. V, pp. 3130-3149.)

That the several quantities of diversion required to produce a lowering of one foot on the several lakes as originally presented were incorrect for the St. Clair and St. Lawrence Rivers, which would be 21,500 and 21,125 cubic fee per second, respectively. (Ray, Vol. V. pp. 2793, 2795; Moore, Vol. V, pp. 2869, 2912; Richmond, Vol. V, p. 2946.)

That a new gaging section had been measured on the Niagara River and that the discharges observed there agreed closely with those at the previously measured locations. (Haskell, Vol. V, p. 2666; Ray, Vol. V, p. 2848; Richmond, Vol. V, pp. 2943, 3013; Shenehon, Vol. V, p. 3143.)

That the discharge of the several lakes at the several gaging stations were controlled by the elevations of the lakes a few minutes before the time of the discharge observation, to wit:

For Lake Huron, Section Dry Dock, sixteen minutes. (Richmond, Vol. V, p. 2948.)

For Lake Erie about eight minutes. (Shenehon, Vol. V, p. 3136); Moore, Vol. V, p. 2874; Ray, Vol. V, p. 2797.)

For Lake Ontario about two and one-fourth hours. (Ray, Vol. V, p. 2804; Shenehon, Vol. V, p. 3137.)

That its time limit is established by the "time interval for a crest of stage to advance" from the lake gage to the section. (Ray, Vol. V, p. 2798). That based upon observations of the "time interval for a crest of stage to advance" in the Sanitary and Ship Canal between Willow Springs and Lemont (Moore, Vol. V, pp. 2880, 2883), it would be possible by opening the gates at the controlling works to increase the flow from 4,167 to 10,000 cubic feet per second at Lake Michigan in two hours and twenty-five minutes, or certainly within three hours. (Ray, Vol. V, p. 2815; Moore, Vol. V, p. 2883.)

For 10,000 second feet diversion the witnesses for plaintiff who testified in rebuttal, found the lowering effect of the 10,000 second-feet diversion at Chicago on the different lakes to be as shown by the following table:

Ref. No.	Witness	Michigan and Huron	Ref. Record	Erie	Ref. Record	Ontario	Ref. Record	
12	Haskell	6.3	V-2663	5.5	V-2662	4.3	V-2727	
13	Ray	5.5 6.7	V-2810 V-2853	5.5	V-2810	5.1 5.6	V-2810	
14	Moore	5.5 7.0	V-2869	5.7 5.5	V-2867	5.2	V-2869	
15	Richmond	5.3	V-2946	5.6	V-2945	5.7	V-2946	
16	Hayford			5.5	V-3091		V-3358	
17	Shenehon	5.7 6.0	V-3142	5.5	VII-725	5.5	V-3159	By Stream Measurements
18	Shenehon	8.2	V-3140			6.4	V-3140	By Method of Fluctuations
19	Shenehon	6.6	II-669			6.4	II-670	By Method of Fluctuations*

* Using ratios derived by defendant's witness, Mr. Gardner S. Williams, but based on 5.5 inches for Erie.

Note—The greater lowerings indicated for Ontario are based on additional measurements made since the earlier testimony; and the same is true in part for Michigan-Huron.

Sur-rebuttal, hydraulic evidence of defendant.

Defendant's sur-rebuttal hydraulic expert witnesses testified and concluded as follows:

That the time required to establish a flow of 10,000 cubic feet per second through the Sanitary and Ship Canal, starting with a flow of 4,167 cubic feet per second was in excess of twenty hours, as demonstrated by experiment, (Wisner, Vol. VI, pp. 3415, 3419; Williams, Vol. VI, pp. 3536, 3537; Cooley, Vol. III, pp. 1788, 1801), and that the full effect of a change of flow was not coincident with the "crest of stage advance" but occurred many hours later, in the said canal, by actual observations. It therefore follows that the assumption upon which the discharges and lake stages had been connected by the plaintiff was erroneous, and the increments or effects of diversion so derived were very greatly in error. (Williams, Vol. VI, p. 3537; Cooley, Vol. III, p. 1773.)

Also, that the position of the meters in gaging the Niagara River at the International Bridge was not that computed by the complainant but further downstream in a larger cross section than that to which the meter registration was applied, and hence the discharge computed was materially too small. (Williams, Vol. VI, pp. 3521, 3531.)

Plaintiff's evidence on damage to commerce on Great Lakes due to the lowering of lake levels on account of the Chicago Diversion.

Plaintiff produced with reference to this subject, in addition to some of the witnesses who testified as to the amount of the lowering effect upon the lakes surfaces due to the Chicago diversion—Mr. Harry Coulby, president of the Pittsburgh Steamship Company (Vol. I, pp. 428-445); William Livingston, president Lake Carriers Association (Vol. I, pp. 200-209).

Plaintiff's witness Eben S. Wheeler (Vol. I, p. 91) states the theory upon which plaintiff's witnesses rely to deduce the damage claimed to commerce.

> "I have said in my notes that lowering means that a definite amount of diversion at Chicago will make the surfaces of Lakes Huron and Michigan a definite amount lower at all times and places than it would have been if the diversion had not taken place. Perhaps I have given too long an answer, the actual elevation of the surfaces of the lakes at any time is the algebraic sum of all the causes which tend to change the elevations. Some of the most important of these causes are rainfall, outflow, evaporation, etc. If two causes, producing opposite effects, are operating at the same time then the actual effect produced will be of the same kind as the larger one, and the amount will be the difference between the two causes. For example, a merchant deposits a thousand dollars each week, and checks out fifty dollars each day, his balance is lowered by the amount he takes out and raised by the amounts he deposits, and in this case the deposits are larger than the withdrawals, therefore his balance will be raised by the difference between the two. At the end of the week it will be raised $650, notwithstanding it was lowered $350 by his withdrawals. Similarly, if for the period, we will say, from 1900 to 1908, the rainfall was greater than the outflow, and evaporation, the lake would rise. This appears to have been the case, notwithstanding the outflow for the period was increased by the diversion at Chicago. A cause which tends to lower the lake itself actually does make the lake lower than it would have been without the cause. I do not know but my answers are a little too long."

Plaintiff's theory is further stated by F. C. Shenehon (Vol. I, p. 286):

> "Lowering is referred to the lake surface which would have prevailed in the absence of the diversion; that is, the lake may actually rise, while this lowering is going on at the same time, in just the same way that a man who is on a railroad train traveling East may reach the tail end of the car he is in by walking westward. It is a case of two movements going on at the same time. This lowering is going on, and it is independent of the other fluctuations that may prevail at the same time."

William Livingston, president of the Lake Carriers Association, stated (Rec. Vol. I, p. 201) that between Buffalo and points in Lake Superior, the depth to which a boat could load could be determined by the depth of water on Ballard's Reef in the lower Detroit River, the reason being that the water crossing Ballard's Reef is a little shoaler than the Lime Kiln Crossing and at Bar Point. If there was another harbor which was shoaler than Ballard's Reef, it would be necessary to take that into consideration, but witness did not know of any; that in loading in Lake Superior the depth at Poe Lock is also taken; that the engineer at Poe Lock keeps a constant gage of the water there; that it does not make any difference if you load to 100 feet outside—the shoalest spot is the one that governs; that the last eight years (Rec. Vol. I, p. 202) has worked a sort of revelation; (He was testifying in May, 1909) in the size of vessels built and operating on the Great Lakes; that approximately seven years ago the steamer A. B. Wolvin was built; that she was the largest vessel on the lake, carrying 3,500 tons more than the next largest vessel; that vessels which have been built since that time, except those built for some specific traffic, say for packing freight, have all been built of her type; that the smallest boat that is built now for business purposes will not run under 7,500 to 8,000 tons; that we have some boats that will carry 12,000 gross tons; that when a boat is loaded to 18 feet or more, the average per inch is 80 to 100 tons; that (Vol. I, p. 204) there are 600 boats that belong to Lake Carriers Association, which is the cream of the carrying capacity on the lakes; that not all of those boats would be affected by the lowering of the lake levels an inch; that about seventy per cent of these boats would be affected; that there are seventy-three ships in the Pittsburgh Steamship Company fleet carrying ore; that these load to nineteen feet, eighteen of them, however, may load to twenty-one feet; that the loss to the ships of the Lake Carriers Association (Vol. I, p. 205) would be over $85,000 per inch, or $500,000 per inch per year for the entire seventy per cent; that the total loss to commerce would be about one-eighth more;

that this would cover the boats not in our association; that larger vessels are being built right along (Vol. I, p. 207) and all the modern vessels could load considerably deeper if the shoalest spots would admit of it; (Vol. I, p. 210); that if the witness or any one else had predicted ten years ago boats would be built of the size of the Wolvin and the present line of boats being builded, that man would have been considered a fit candidate for a medical asylum.

Harry Coulby, president of the Pittsburgh Steamship Company testified (Vol. I, p. 428):

That Pittsburgh Steamship Company boats are engaged principally in carrying ore, coal and sometimes grain between Two Harbors, Duluth, Superior, Ashland, Marquette, Escanaba and the Lake Michigan ports, Milwaukee, South Chicago, Chicago, Gary and to all lower lake ports such as Cleveland, Buffalo, Erie, Conneaut, Ashtabula, Fairport, Lorraine, Huron, Sandusky and Toledo; that the company owns 106 vessels and employs or charters 100 more during the season; that there are 61 of these vessels that are capable of loading to twenty feet or more; that the depth to which boats going to Lake Superior may load is determined by the depth of water at the Poe Lock at Sault Ste. Marie; that as to those boats which are not going to Lake Superior, Ballard's Reef and the shallow waters across Lake St. Clair determine the depth; that the present depth at the time of testifying (July 8, 1909) was nineteen feet three inches at the Poe Lock and twenty feet Ballard's Reef, and the shoals of Lake St. Clair; that the large vessel makes about twenty-five trips a season; (Vol. I, p. 431); that every time you reduce the carrying capacity of a boat, you reduce the earnings that much without reducing the operating cost; (Vol I, p. 432); that all the harbors have been dredged out to take care of the ships that come over what the witness calls the "necks of the bottle"—that is, the Poe Lock and Ballard's Reef; that the harbors along the south shore of Lake Erie would be affected by lowering of the water surface; that each

inch of loss of depth on the sixty-one ships affected of the Pittsburgh Steamship Company's fleet, assuming twenty-five trips for each boat per season, and 100 tons for each inch loss of depth per boat per trip, causes a loss in total carrying capacity per inch of 152,000 tons per season; that 12 ships of the 61 may load to 25 feet. (Vol. I, p. 434.)

Cross Examination.

Pittsburgh Steamship Company corporation of West Virginia, and its stock is owned by the United States Steel Corporation; it carries ore for the United States Steel Corporation only.

The report of the Board of Engineers on Waterways from Lockport, Illinois, to the mouth of the Illinois River, dated August 15, 1913, (Rec. Vol. IV. p. 2587) signed by two of the plaintiff's witnesses, states the plaintiff's claims of damage to commerce:

> "The largest lake freighters recently built carry over 80 short tons of freight for each inch of loaded draft, and an uncompensated Chicago diversion of 10,000 second feet would cause a loss to each vessel of at least 446 tons in carrying capacity for each down trip through the channels connecting with Lakes Michigan and Huron. This, based upon 25 trips per season, with vessels returning light, means a loss of at least 11,150 tons per year, and at a freight rate of 55 cents per ton represents a monetary loss of at least $6,000 per large vessel per year. During the season of 1912 there passed through the locks at Sault Ste. Marie over 72,000,000 tons of freight, the greater part of which was carried in vessels of such size as to be affected by any loss of depth caused by a Chicago diversion. The tonnage of 1913 bids fair to exceed the tonnage of 1912. The lowest estimate of the loss to American vessels alone that has been brought to the attention of the Board is over $1,000,000 per annum, and the loss will increase with the increase in the number and size of vessels."

Defendant's evidence relating to damage to commerce, assuming a lowering of lakes surfaces due to the Chicago diversion.

Major Charles Keller, one of the witnesses for the plaintiff, made a study of this question, a report of which is contained in the report of the Board of Engineers entitled "Waterway from Lockport, Illinois, to the mouth of the Illinois River," dated August 13, 1913, and made pursuant to the Rivers and Harbors Act of June 25, 1910. The report of Major Keller contains the following (Rec. Vol. IV, p. 2608):

> "6. With the outlets free of ice at any instant the volume of water discharged from one of the lakes is a definite quantity fixed by the level of the lake. With a constant supply of water and constant evaporation there would then be no change in the elevation of the lake's surface, except such temporary changes as might be caused by winds and barometric disturbances. But the flow into each lake is, as has been explained, constantly varying, and while the discharge from the lakes is also ever changing, so as in the long run to tend to counterbalance changes in supply, yet these adjustments of supply and discharge are not simultaneous,and the surface levels of the lakes are therefore, constantly fluctuating, as is readily seen from the plates attached.
>
> 7. These regular but uncontrollable changes in lake level mask the effect produced by an artificial diversion."

The plates referred to in the above quotation show hourly gage readings at different gaging stations, indicating the changes in surface elevations of Lakes Michigan and Huron for different months. Opposite is, as an example, one of these plates covering the month of August, 1911, (Rec. Vol. IV, p. 2653):

Lyman E. Cooley, whose qualifications as a witness for the defendant have been heretofore stated, testified (Rec. Vol. III, p. 1776):

In my opinion lowering of the levels of Lakes Michigan and Huron five to six inches, Erie somewhat less, Ontario somewhat less than Erie, would cause no injury to navigation. The changes which have been made which influence the lakes' levels since the improvement of lakes' channels was undertaken, exceed in several instances all the changes pro-

War Department.

House Doc. No. 762, 63d Cong., 2d Sess.

duced or alleged to be produced by the diversion at Chicago, and such changes have not been considered worthy of attention, nor have they occasioned any protest or comment by lake carriers.

Again, the amount of change alleged is nominal in comparison with fluctuations that are going on by hour, by day, and through the months and the year. And vessel owners are obliged to load safe for the trip, and give a very much greater margin of clearance beneath the boat than is indicated by the alleged change.

Again, it is not competent to estimate the effects as a diminution in a fixed plane of reference, or as the difference between a fixed plane of reference and the bottom, as made in a canal or other absolutely still body of water; and the estimates that have been made up have been framed on that basis, and do not recognize these oscillations and changes in level which occur many times in the course of the trip.

Again, it is recognized as sound practice to provide a margin beneath the boat, not of inches, but of feet. As early as 1888 I made a study of that question and wrote a paper to the effect that the future ship canal should have a depth of not less than twenty-five per cent of its draft beneath the keel. The International Congress on Navigation at Philadelphia, year before last, declared as one of the principles which govern restricted channels and canals, that it should have a depth of at least one meter beneath the keel, depending, of course, upon the character of channel and the speed which was to be considered. And the same proposition is worked out by Colonel Black, an engineer officer of the United States Army (later Chief of Engineers) in his recent report on the Hudson River. Colonel Black lays down the proposition that the river should have a depth of two or three feet of clearance beneath the boat, and gives some remarkable data in regard to the effect of the Hudson River boats attempting to navigate with the restricted limit beneath the

boat, and also for the further reason that any item of cargo that would fall off the boat, like a barrel of cement, would roll the skin and frame out of the bottom of the boat if it happened to strike it. There should be enough clearance there for safety. I know from my own experience in navigation on western rivers, that a boat that would attempt to run within a foot or two of the bottom would be utterly uncontrollable in passing through the channelways of the lakes. So that a mere margin of a few inches would not be thought of by practical navigators; would not be accounted for and would not be known to exist, in the absence of a specific knowledge of a diversion of something of that kind existing at Chicago.

On the other hand, a lowering of the lakes by one foot, better by two feet, would be a profound advantage to every lake city about the Great Lakes, in giving a better freeboard for its sewer system and better elevation to its docks. All the cities about the lakes are built on low ground, margining some creek originally awash at high water of the lake, and the benefits of such a lowering to the sanitary welfare of the cities about the Great Lakes would be so great in proportion to the cost of producing two feet additional depth in all the harbors and channels of the lakes, that it would be a vanishing quantity. And, furthermore, I conceive that if there were not diverse jurisdictions in the matter, but were one jurisdiction that looked at public welfare as a whole, a proposition of that kind would be a proposition to at once elicit legislative attention.

Isham Randolph, a resident of Chicago, a civil engineer, a contemporary of Lyman E. Cooley, for a number of years Chief Engineer of the Sanitary District of Chicago, later its Consulting Engineer, and at one time a member of the Isthmian Canal Commission, testified as follows (Rec. Vol. VI, p. 3595):

In the report of the Board of Engineers on Deep Waterways from the Great Lakes to the Atlantic, 1901, p. 219, (Rec. Vol. IV, p. 2390), it is stated:

> "The speed attained by a ship in open sea will be reduced to a marked degree on entering shoal water, even of unlimited width."

On page 220 of the same report:

> "Retardation in shoal water. * * * Observations made recently on the freight steamship Angeline, in the deep water of Lake Huron and the shoal water of Lake St. Clair, indicate that the retardation is about 18 per cent. (Note, the Angeline is 414 feet long and 51 feet beam; was built in 1899.) The depth under the keel was about 2 feet 10 inches, no allowance being made for settlement of the ship in the water which always occurs when the water is shoal.
>
> The Senator (410 feet by 45 feet) is also cited with a loss of 16 per cent. in Lake St. Clair. This Commission provides for two feet of depth below the keel of vessels for which they designed a channel."

Kent's Engineers' Pocket Book, 1900 Edition, treats of this subject on page 1007. (Rec. Vol. VI, p. 3596, 3597.)

> "The Medusa, a third class cruiser, length 265 feet, beam 45, draft 16 feet 6 inches, displacement 2,880. Indicated horse-power for ten knots per hour, 700; for 14 knots per hour, 2,100; for 18 knots per hour, 6,400; for 20 knots per hour, 10,000.
>
> Atlantic passenger steamer 525 feet long, 63 feet beam, mean draft on trial 21.3, displacement 11,550 tons; indicated horse-power 10 knots per hour, 2,000; for 14 knots per hour, 4,600; for 18 knots per hour, 10,000; for 20 knots per hour, 14,500.
>
> The Medusa's figures for 20 knots are from the trial in Stokes Bay and show the retarding effect of shallow water. The figures for the other ships for 20 knots are estimated for deep water."

Here we have an example of two vessels, one having a displacement of about four times that of the other. The larger requiring in deep water only forty per cent more power to

give it twenty knots speed than was required to give the smaller vessel the same speed in shallow water.

On pages 34 and 35, Colonel Black says: It is believed that the minimum clearance allowable for safe navigation in the Hudson River is two feet. In Germany, the clearance adopted as safe is one meter (39 inches).

Captain Marshall states in the report of the Chief of Engineers for 1893, Appendix LL, pages 2798, 2799, in discussing the clearance over tunnels under the Chicago River (Rec. Vol. IV, p. 2370): "There should be at least two feet between the bottoms of vessels and the crowns of the tunnels to guard against chance obstructions of small extent lodging temporarily over the ridges crowns."

The witness further stated:

I am of the opinion that the amount of water that should be under the keel of a boat is a matter of feet rather than inches. If there were three feet under the keel and the depth was decreased so that there were six inches left, the effect upon navigation would be in loss of speed and increased consumption of coal on a trip from Lake Superior to Cleveland, considering the shallow places in the St. Clair and Detroit River. The increased consumption of coal under such conditions would be negligible and it must be borne in mind that through those channels the heavy loads are going with the current and they come light up-stream.

Joseph Ripley, for a great number of years in the employ of the United States Engineer Corps, and whose qualifications as a witness for the defendant have been heretofore stated, testified as follows, July 24, 1913, (Rec. Vol. III, pp. 1304, 1305):

The elevation of the floor of the Poe Lock is 562.37 above sea level. The lower mitre still is located opposite the gate recesses of the lower gate and the intermediate gates. The floor of those recesses is a foot and a half lower than the

general floor of the lock. The mitre sill is either four-
1305 teen or sixteen inches in height. Below the mitre sills for the intermediate gates and also for the lower lock gates, are platforms built of 12x12 timbers; the platforms being, as I remember it, some thirty feet along the axis of the lock. Below the lower guard gates, a platform was built which is .33 of a foot, or about four inches higher than the floor of the lock. The Poe Lock was opened for navigation in August, 1896; but the depth over the mitre sills was not available to navigation purposes until the spring of 1898 as the sill and platform for the movable dam located across the canal about 3,000 feet west of the Poe Lock was left in place until that time, and on that guard gate sill, the depth was only seventeen feet.

The opening of the West Neebish Channel in 1907 made the Poe Lock the critical place as to the depth of water for navigation purposes in the St. Mary's River, which has been the case since that time. The platform of the Poe Lock is the critical place, that is, the one I describe below the guard gates. The platform was placed for the purpose of protecting the lower mitre sill of the lock, but is really of no value because the platform directly below the sill could be utilized for that purpose, and that would not necessarily be any higher than the general floor of the lock. This platform could be removed at a cost of not exceeding $10,000 in the
1297 winter season without interfering with navigation.

In making improvements on the Great Lakes, a reference plane was fixed which was a certain elevation above sea level. This reference plane for an improvement is fixed by the engineer officer at Detroit upon recommendation of his assistants, and this reference plane becomes a matter of record in
1298 the Department. Prior to 1903 the improvements in the channels of the Great Lakes were referenced to a water surface assumed to be 584.37 above sea level at the foot of the St. Mary's locks and 581.47 at Mud Lake. This was the reference plane. In the 1903 project, however, the improvements were here referenced to an assumed water surface of 580.37

above sea level below the locks and 578.77 in Mud Lake, the variation between those points corresponding to the slope of the river. These were the reference planes for the
1299 improvements. When the channel improvements are made, it is provided that they shall have a depth of a certain number of feet below the reference plane. The reference plane for the 1903 project improvement in the St. Mary's River was fixed when the project was prepared. The depth of the improvement of course had to be
1300 stated so it would be incorporated in the Act of Congress authorizing the improvement, and as the prior improvements had been referenced to the mean stage of water as determined in 1870, and the water at times was below the mean stage, it would not provide navigation for the implied depth of the improvement. As the department had ruled that for appropriations made along the sea coast the depth should be referenced to low tide, I urged Major Bixby to reference the improvements in St. Mary's River to the lowest stage of water we had, or the probable lowest stage that we would have, and with his approval I prepared the grade plane as stated. This was in 1902. Major Bixby was at that time the engineer officer in charge at Detroit. I gave consideration to the probable lowering of the Lake Huron water surface due to the Chicago diversion, as indicated by the reports with reference to the gagings of the St. Clair River made by
1301 Louis C. Sabin, a witness for the plaintiff. The Chicago Canal had been opened at that time, and the gagings of the St. Clair River had been made and some discussion had been had with reference to the amount of the lowering which would be caused by the diversion by the Chicago Drainage Canal. I had discussed this matter with Mr. Eben S. Wheeler, Major Bixby and my assistant, Benno Rohnert. In fixing the plane, I intended that if we had an improvement for
1302 twenty-one feet that that twenty-one feet should be available for navigation on all occasions during the navigation season. The reference plane which I prepared was the one used for the 1903 project improvements in the St.

Mary's River and its lower channels. I fixed a different reference plane than I would have fixed had there been
1304 no diversion at Chicago. Under the 1903 navigation improvement project excavations and dredging were made in the channels of the St. Clair and Detroit River at different points. In 1901 some improvements were made for a twenty foot depth, reference plane being 571.5 above sea level. In 1904 improvements were made in the Detroit River for a twenty-one foot depth. The reference plane, however, for that was fixed at 571.0 feet above sea level.

Francis C. Shenehon, one of the plaintiff's hydraulic witnesses, stated that there are records of Lake Erie rising as much as eight feet in about eight hours (Rec. Vol. V, p. 3176); Lake Michigan as much as five feet in a very short time.

Herbert Charles Sadler, witness for the defendant, July 15, 1913, (Rec. Vol. III, p. 1240):

Residence Ann Arbor, Michigan; Professor of Naval Architecture and Marine Engineering, at University of Michigan, since 1900; educated at Dulwich College, England, and at Glasgow University, Scotland, latter degree of Bachelor of Science in Engineering in 1893; Doctor of Science from same U. in 1902; 1890-1896 engaged in practical shipbuilding on the Clyde; 1896-1900 Assistant Professor of Naval Architecture and Marine Engineering at Glasgow U., and during that time associated with Prof. Biles in consulting practice; 1901-1904 appraiser for the vessel properties in connection with the Michigan Railroad appraisal; appraised the vessels owned by the Duluth, South Shore & Atlantic in 1912; consulting naval architect for the City of New York in connection with municipal ferries; also for Great Lakes Engineering Works having one of the largest ship yards on the Great Lakes. Last two years acted as consulting engineer (testifying in July, 1913) for the Tow Boat Board of United States Army Engineers Corps, the Board consisting of Lt. Col. Lansing H. Beach, Major Charles Keller, and Col. Newcomber; con-

sulting naval architect for the White Star Line of Detroit; for the Detroit & Cleveland Navigation Company and for the Hudson River Day Line, New York.

1243 *He testified as follows*: The freight per year of all kinds on the Great Lakes, exclusive of package freight—that is Lake Superior, Huron, Michigan, Erie—freight that is carried through the St. Mary's Falls Ship Canal and the St. Clair and Detroit Rivers, as shown by the statistical report for 1912, is 72,472,676 tons, the ore tonnage being between forty and fifty millions; wheat 5,220,000 tons; coal 14,-
1244 900,000. The ships carrying this ore are 440x52x28 feet, 550x56x31 and 605x58x32 feet; first class 440 feet—there are 151 boats; 550 feet class, 93; 605 feet class, 73; 440 feet class are designed to be loaded to 19 feet; 550 feet class to 19 feet and the 600 feet class to 19 feet. It might be possible to load the two larger types to somewhat deeper draft.

The cost of constructing new boats to have the same carrying capacity with a less draft of one, two, three, four, five or six inches, has been estimated. 440 feet class, loss in
1245 capacity for 1 inch draft, 55 tons, would require an increase in length of about 2.1 feet for each inch; increased cost of vessel, $1,000; interest and depreciation, $100. For 3 inches less draft, increase in cost would be $3,000; interest and depreciation about $300. For 550 feet class, loss in capacity for 1 inch less draft, 70 tons; increase in length required to take care of this, would be 2.9 feet; increased cost of vessel $1,700; interest and depreciation, $170; for 3 inches loss the increased cost of vessel would be $5,100; interest and depreciation, $510; for the 605 feet class, loss in capacity for 1 inch would be 81 tons; increased length 3.1 feet; increased cost of vessel $1,800; interest and depreciation $180; for 3 inches loss in draft, increased cost of vessel $5,400; interest and depreciation $540. The three classes men-
1246 tioned carry about 70 per cent of the total of ore, coal and wheat; 48 per cent by the first class; 26 per cent by the second, and 26 per cent by the third. The cost of operating

the boat designed of the greater length to take care of the decrease in draft, would be no more than vessels con-
1247 structed in the present manner. All of the 500 and 600 feet class of boats have been built and put in service in the last 13 years; that is, since 1900. The 500 and 600 feet classes are the only boats that are designed to be loaded
1248 to more than 19 feet draft.

The cost of building the 93 vessels of the 500 feet class to take care of loss in draft of 3 inches, would be $1,404,300, and the 73 vessels of the 600 feet cost $1,197,200. These amounts represent the actual cost of construction and
1250 the capitalized interest and depreciation amount.

The cost of transporting tonnage carried by the vessels of the 500 and 600 feet classes for each inch of loss of draft is 0.116 cents per ton per inch. For the 73 vessels above
1251 mentioned for 3 inches of loss of draft, the loss would be per year, $42,480. for 15 trips, $56,700 for 20 trips and $70,950 for 25 trips; for the 93 vessels above mentioned, the loss would be for 15 trips, $49,950; for 20 trips, $66,390; for 25 trips, $82,860. Capitalizing these yearly amounts, the estimate of total loss, is 15 trips, $1,848,600; for 20 trips, $2,-461,800; for 25 trips, $3,076,200 loss. It is estimated that 37 million tons were carried by these two classes of vessels
1252 for the year 1912. The loss per year would be for 3 inches, $128,760. Capitalizing this at 5 per cent, equals $2,575,200 as the total loss.

Henry C. Adams (Rec. Vol. III, p. 1354; September 25, 1913), a witness for defendant:

Resides Ann Arbor, Michigan; Professor of Political Economy & Finance, University of Michigan, since 1887; prior to that time lectured Cornell U., Johns Hopkins and Michigan; in 1888 and until 1907 was statistician to the Interstate Commerce Commission; 1910 had charge of what is known as the determination of the intangible values of the Michigan Valuation of Railroads; was going to China shortly

as advisor to the Chinese Government as to standardization of Chinese Railway Accounts.

The witness testified as follows: I have examined the testimony of Mr. William Livingstone, witness for the plaintiff. He has computed the annual loss to commerce on the Great Lakes, assuming a depreciation of the normal lake level of 6 inches, to be $4,387,500. I think he is incorrect in this for he has multiplied the loss of load by the rate for carrying the ore, without taking into consideration the increased expense incident to that increased freight carried. Furthermore, this is incorrect in that the average number of
1372 trips for all vessels is 11.6, instead of 20 round trips, testified to by Mr. Livingstone, and 25 round trips, as testified to by Mr. Coulby. I agree with Mr. Livingstone, however, that the damage is confined to those boats
1376 carrying ore or to the ore traffic. I find that the average round trip for those boats loading to beyond 18.1 feet passing through the St. Mary's Falls Ship Canal, is 14.12 per year.

Joseph Ripley, witness for the defendant, whose qualifications have been heretofore stated, July 24, 1913, (Rec. Vol. III, p. 1306), testified as follows:

The cost of deepening the channels of the St. Mary's River, St. Clair, the channel in Lake St. Clair and those of the Detroit River, 4 inches or 8 inches, would be, for 4 inches, $163,990; 8 inches, $403,854. The cost for deepening in inches intermediate would be proportional. Including (p. 1307) the channels connecting the Great Lakes, the harbors of the United States and Canada, the cost of deepening 4 inches is $2,163,454; 8 inches is $4,405,008; capitalized maintenance for 4 inches, $728,510, and for 8 inches, $1,092,766 capitalized.

CHRISTIE EXHIBIT II, APRIL 26, 1923.

AFFIRMATIVE EVIDENCE ON BEHALF OF DEFENDANT, TO WHICH PLAINTIFF DID NOT INTRODUCE OR OFFER EVIDENCE IN REBUTTAL.

Compensating or regulating works to off-set for the lowering of lake levels and connecting channels of the Great Lakes.

July 12, 1920, the defendant filed a motion for a decree only enjoining it from diverting at Chicago in excess of 10,000 cubic seconds feet of water, on condition that it should defray the cost of building such compensating or regulating works as the United States or proper authorities might provide, to off-set for the lowering of the levels of the Great Lakes and their connecting channels, due to the Chicago diversion. As grounds of said motion, various facts were alleged. The motion was heard and denied by the Court upon the allegations of facts set forth in said motion, without the introduction of evidence in support of or in opposition to the issues raised. The motion and the facts alleged therein as grounds for said motion, have been heretofore set forth. See This Narrative, (p. 98).

Among other things, it was alleged in said motion that it was an undisputed fact in the record that it was feasible and practicable to construct compensating or regulating works to off-set for the lowering of the lake levels due to the diversion at Chicago, and **various portions of the record were referred to as sustaining this allegation, among others, the following:**

John R. Freeman, witness for defendant, civil engineer, whose qualifications have been heretofore set forth (Rec. Vol. III, p. 1173; This Narrative, p. 135), April 4, 1913, testified as follows:

Compensating works, called the Gut Dam, were built by Canada at the outlet of Lake Ontario. The probable effect of this dam was estimated by U. S. Engineers prior to the building and later found to be substantially correct. It raised

the level of Ontario greater than the estimated lowering that would result from greatest proposed diversion at Chicago. Also, at the outlet of Lake Superior, near the International Bridge, an obstruction was built. Its general effect was to raise the level of Lake Superior about six inches. At the outlet of Lake Erie compensation works were built near Black Rock and have had the effect of raising the level of the lake. A still more radical plan for raising the level of Lake Erie was presented in the Report of Engineers on Deep Waterways.

Properly designed compensating works constructed immediately below the outlet of Lake Huron, would cause the lessening of the high slope and injurious currents could be avoided by means of a series of wing dams, so that there would be no objectionable velocity, and compensating works for Lake Erie and Huron could be constructed for approximately a million dollars.

Joseph Ripley, witness for the Sanitary District, whose qualifications have been heretofore stated (This Narrative p. 137) testified as follows (Vol. III, p. 1310):

The distinction between compensating and regulating works is that the former consist of fixed weirs and the latter is a combination of fixed weirs and movable dams. The effect of such works would be to increase the depth of the lake and make certain a continuance of such depth. A dam could be constructed in the St. Clair River about 1,300 feet up stream at Bunce Creek. Another dam could be located in the Detroit River in the Stony Island section. Also a dam placed in the Niagara River either near the upper end or down below Tonawanda would provide for the regulation of Lake Erie. These works would cost anywhere from $1,400,000 to $3,950,000, depending upon type of dam and the extent of the regulating feature; the St. Lawrence River from $200,000 to $1,000,000. The level of the lakes would thereby be raised from four inches to one foot.

The regulating works in the St. Clair River would lessen the current at Fort Gratiot which is the place of the swiftest current in the St. Clair River, and would thereby benefit navigation.

Gardner S. Williams, consulting engineer; Ann Arbor, Michigan, witness for the defendant, whose qualifications have been heretofore stated (Rec. Vol. II, p. 743; This Narrative p. 134) testified:

The backing up of the Upper Detroit River by the Livingstone Channel works and the raising of Lake Ontario by the Gut Dam in the St. Lawrence, illustrate the ease with which it is possible to compensate for diversions from Lake Michigan. It would be entirely feasible to close the Stony Island Channel and thereby reduce the discharge of the lower Detroit River by about 11,000 cubic seconds feet, which would raise Lake St. Clair in the neighborhood of two inches. The capacity of the Trenton Channel, which was found to be about 36,000 cubic feet seconds, could be easily reduced to an extent equal to the reduction of the Stony Island Channel or even more by a judicious filling in of material, and thus the compensation of Lake St. Clair obtained for the diversion at Chicago. The cost of this filling based upon the prices paid for moving the material in the vicinity of the mouth of the Detroit River, would be about $250,000. The total discharge of several channels at the mouth of the St. Clair is 194,000 cubic feet seconds. This total might be restricted to the extent of 15,000 cubic feet seconds without detrimental effects, and this would compensate for lowering Lake Michigan—Huron by the contemplated Chicago diversion. The cost of this compensation would be about $500,000, which makes a total of about $750,000 to compensate for the lowering of Lakes Michigan—Huron, the St. Clair and the St. Mary's, St. Clair and upper Detroit Rivers. The construction of the Gut Dam in the St. Lawrence has already compensated for the abstraction of water from Lake Ontario; and the International Waterways Commission are submitting a report

upon works to regulate the level of Lake Erie, which, if constructed, would provide for a compensation for the diversion from Lake Erie and the lower Detroit River.

The Rivers and Harbors Act of June 25, 1910, provided for the creation of a special Board of Engineers to make a report upon a waterway from Utica to the mouth of the Illinois River "and upon such measures as may be required to properly preserve the levels of the Great Lakes, and to compensate, so far as practicable, for the diminished level in said lakes and the connecting waters thereof by reason of any diversion of water from Lake Michigan for the maintenance of the proposed waterway herein described, or diversion for any other purpose."

The Special Board made its report August 15, 1913, to the Chief of Engineers, U. S. A. The board consisted of William H. Bixby, Brigadier General of the United States Army, retired president of the board, C. McD. Townsend, one of the witnesses for the plaintiff here, Colonel Corps of Engineers, United States Army, C. Keller, also a witness for the plaintiff, Major, Corps of Engineers, United States Army, J. B. Cavanaugh, Major, Corps of Engineers, United States Army, and John Bogert, civil engineer.

The above mentioned report before it was sent to Congress, thereafter known as House Document 762, Sixty-third Congress, Second Session, was reviewed by the Board of Engineers for Rivers & Harbors, and report made thereon. That report, including the report of the Special Board, so far as they are material, are as follows (Rec. Vol. IV, p. 2576-2590):

Report of the Board of Engineers for Rivers and Harbors.

[Second Indorsement.]

BOARD OF ENGINEERS FOR RIVERS AND HARBORS.

December 16, 1913.

To the Chief of Engineers, United States Army:

1. The Board of Engineers for Rivers and Harbors has had under consideration the final report of the special board of engineers.

* * *

I. FEASIBILITY OF THE WATERWAY.

2578 3. In the valley of the Desplaines and Upper Illinois Rivers, excellent foundations for locks are available; the lower Illinois has a gentle slope, so that any reasonable depth can be obtained by dredging, and the present diversion of water from Lake Michigan through the Chicago Drainage Canal is more than sufficient for navigation purposes. It is therefore the opinion of the special board that the waterway from Lockport to the mouth of the Illinois River is feasible.

II. THE MOST ADVISABLE DEPTH AND DIMENSIONS FOR THE WATERWAY.

4. In determining the most advisable depth for the waterway, the special board gives consideration to the character, origin, and destination of the probable commerce, and the type and dimensions of the vessels best suited to handle the traffic. It states that if the waterway is to be used by vessels capable of navigating the ocean and the Great Lakes, it should be given a depth suitable for the economic carrier now used on those bodies of water, which would fix the depth at not less than 24 feet; but if it is to be constructed for vessels adapted to river traffic, navigation does not require its depth to exceed 9 feet. A depth of 14 feet, which has been frequently urged for this waterway, is greater than necessary for river navigation and entirely insufficient for either lake or ocean vessels. A uniform depth on the Mississippi and its leading tributaries will be far more beneficial to the navigation interests of the United States than a main channel of great depth with shallow feeders. As a channel of 8 feet depth is now maintained from Cairo to St. Louis, and can be extended from St. Louis to Utica, on the Illinois river, at relatively small cost, business caution dictates that a waterway of this depth be obtained and tested before entering upon enormously expensive projects of questionable utility.

5. The special board considers a bottom width of 160 feet in canal and 200 feet in the open river above the mouth of the Illinois sufficient for a channel of 8 or 9 feet
2579 available depth. For safety and ease of navigation, the channel should be excavated to 11 feet in rock cuts and canals, and the locks should be given 11 feet depth, 80 feet width, and 600 feet usable length. A waterway of these dimensions would have a capacity exceeding 100,000,000 tons per annum.

III. CO-OPERATION WITH THE STATE OF ILLINOIS.

6. A project has been presented by the State of Illinois which contemplates the development of water power at four sites between Lockport and Utica, and the improvement of navigation by the construction of five large locks, 80 by 900 feet in horizontal dimensions, with 24 feet depth on their miter sills. This project proposes the utilization for power purposes of the water which may flow through the Chicago Drainage Canal and contemplates an ultimate channel depth of 24 feet for navigation purposes, though the estimates, amounting to approximately $20,000,000, provided for 24 feet only to Brandon Bridge and for 14 feet below. The special board states that the waterway proposed is more that sufficient for any probable navigation. It believes that the General Government will fully cooperate with the State in a waterway from Lockport to the mouth of the Illinois river if it assumes charge of the State structures at Henry and Copperas Creek, and enlarges the existing channel in the Illinois river below Utica to suitable dimensions.

IV. CONDITIONS NECESSARY IN CONNECTION WITH COOPERATION TO FULLY PROTECT THE INTERESTS OF THE UNITED STATES.

7. The special board states that a primary condition of any cooperation between the United States and the State of Illinois should be the acceptance in perpetuity of full responsibility by the State of Illinois or its agencies for all damages by changes in lake levels, including cost of compensating works, and for all damages to riparian owners, and the State should transfer to the United States the locks and the control of the new waterway thus created so far as needed by navigation, and the locks and dams at Henry and Copperas Creek on the Illinois river. With such a transfer the obligations of the State of Illinois to the United States with reference to the maintenance of the Illinois and Michigan Canal may be considered as adequately fulfilled, and any
2580 equities of the United States in the rights of ways and other properties of this canal should be transferred by the State of Illinois. The special board believes that should the State of Illinois be unable to complete the locks suggested by the board or the bridges required by navigation, the United States might then properly undertake to complete these parts of the project.

VI. SUCH MEASURES AS MAY BE REQUIRED TO PROPERLY PRESERVE THE LEVELS OF THE GREAT LAKES, ETC.

2581 9. The investigations and studies of this special board show that the diversion of water from the Lakes lowers the levels progressively in proportion to the amount so diverted, the full effect not being observable for some time; and that for the 10,000 second-feet diverted through the Chicago Drainage Canal, at mean lake level, the water surface will be lowered in Lakes Huron and Michigan 0.465 foot; in Lake Erie, 0.448 foot; in Lake Ontario, 0.431 foot. Such lowering would materially affect the carrying capacity of the large freight vessels, estimated at 88 tons per inch of draft, and would cause a loss on American vessels alone at the lowest estimate of $1,000,000 per annum.

10. Three methods for compensating for such diversion have been considered by the special board: (1) By the construction of submerged weirs with arbitrarily controllable sluices at the lower ends of the Lakes; (2) by reducing the area of the natural outlets by the construction of fixed contraction works therein; (3) by dredging harbors and connecting channels. The investigations of the board show with certainty that the result of diversion of water through a new outlet is a lowering of Lake level. The effect of the great storage capacity of the lakes and of the natural fluctuations of level due to natural causes, such as the varying amount of rainfall and the varying amount and direction of wind pressures, is such that the absolute level at a given time at any given place can not be predicted, and human wisdom is inadequate to regulate a variation of discharge through the outlet in such a manner as to produce a definite desired result. Method No. 1 therefore must be classed as impracticable. Compensation by dredging is practicable, but on account of the extensive areas involved, this method would be unduly costly. Of the three methods, the second only is therefore favorably considered. The special board proposes to hold up the level of Lake Erie by the construction of three submerged wiers in Niagara River, at an estimated cost of $150,000, and that of Lakes Michigan and Huron by submerged weirs in St. Clair River, at an estimated cost of $325,000, the total for compensating works being $475,000, with $15,000 annually for maintenance.

* * *

CONCLUSIONS.

2582 14. After due consideration of the reports of the special board the Board of Engineers for Rivers and Harbors concurs in general with the views and conclusions expressed therein. With the information now available, it is not prepared to indorse certain details of the discussions in the appendixes and elsewhere pertaining to the regulation of the level of Lake Superior,
2583 the regulation of the day and night discharge at Niagara Falls, and the estimates of cost for the dams across the Mississippi River. But inasmuch as this difference of opinion on these points does not affect the final conclusions, the board believes that nothing would be gained at this time by pursuing its investigation further. The board concurs fully with the general conclusions expressed by the special board in its final report, but differs slightly from those given in its preceding report. In this connection attention is invited to the following statements made by the Board of Engineers for Rivers and Harbors in its report of January 30, 1911, printed in House Document No. 1374, Sixty-first Congress, third session:

> It does not concur with the view of the special board that the United States should assume that part, if any, of the cost that is in excess of $20,000,000 for constructing the portion of the waterway between Lockport and Utica. Moreover, it suggests that the amount of diversion to be permitted from Lake Michigan should be determined, if practicable, before the project is undertaken.
>
> * * *
>
> It is understood that the sanitary district of Chicago and the State expect to develop considerable water power on that portion of the waterway between Chicago and Utica. As it is proposed that the navigable channel between these points shall be built without cost to the United States, it is believed that the General Government should relinquish to these local agencies any rights that it may have in the power to be thus developed. It does not appear that there is any question of water power, flood control, or other matter that can be coordinated with that portion of the work to be done by the United States for the improvement of navigation, so as to lessen the cost and compensate the Government for its expenditures made in the interest of navigation.

In conclusion it is recommended that the work proposed by the special board for the United States in the Illinois River be not undertaken until the Secretary of War has received satisfactory assurance from the State of Illinois that the State will build that portion of the waterway from Lockport to Utica without cost to the United States, and in accordance with plans to be approved by him; and, further, until the interests of the United States
2584 have been satisfactorily safeguarded as indicated by the special board, viz., that the State of Illinois, or its agencies, shall assume entire responsibility in perpetuity for all damages by changes in lake levels incident to the work, including cost of compensating works, and for all damages to riparian owners along the proposed waterway from Lake Michigan to the mouth of the Illinois River, and that the State shall transfer to the United States the locks and the control of the new waterway thus created so far as needed for navigation, and the locks and dams at Henry and Copperas Creek on the Illinois River.

15. It is the distinct recommendation of the Board of Engineers for Rivers and Harbors that the term "control of the new waterway thus created so far as needed for navigation" shall be interpreted to include such control of the use of water for power purposes as shall be necessary to insure the conditions of flow required for navigation. Further, the board believes that the total volume of water to be diverted from the natural discharge channels of the Lakes should be definitely fixed by Congress; that a project, with estimate of cost, for works necessary to compensate for such diversion should be prepared to the satisfaction of the Chief of Engineers and the Secretary of War; that before any diversion is made beyond that at present existing, the State of Illinois shall transfer to the Secretary of War the funds necessary for such works as given by the approved estimate of cost; that the works shall be built by the United States with the funds so provided; and that the control and maintenance of such works shall be in and at the cost of the United States.

16. As indicated above, the work proposed by the special board involves an original outlay by the United States of $1,050,000 for the Illinois River and $3,710,000 for the Mississippi River, or a total of $4,760,000, and provides for a navigable channel depth of 8 feet from Utica to St. Louis. The act ordering the investigation

appropriated $1,000,000 "for the construction of a waterway from Lockport, Ill., by way of the Des Plaines and Illinois Rivers to the mouth of said Illinois River," and provided that "until these plans and estimates have been submitted and a project adopted by Congress the appropriation of $1,000,000 herein made shall not be available for expenditure." If the project be adopted by Congress, this conditional appropriation should be
2585 made available for the improvement as a whole, and subsequent appropriations should be made with a view to completion of the work in four years. The Board of Engineers for Rivers and Harbors recommends the adoption of the project under the conditions stated above.

For the Board:

W. M. Black,
Colonel, Corps of Engineers,
Senior Member of the Board.

Final Report by a Special Board of Engineers on Waterway from Lockport, Ill., to Mouth of Illinois River.

New York City, August 15, 1913.

From: A Special Board of Engineers.

To: The Chief of Engineers, United States Army.

Subject: Report on waterway from Lockport, Ill., to the mouth of Illinois River, and on certain related subjects.

The Board of Engineers appointed by the Secretary of War September 8, 1910, in Special Orders, No. 43, Office of the Chief of Engineers, for the consideration of a waterway from Lockport, Ill., by way of the Des Plaines and Illinois Rivers, to the mouth of the said Illinois River, in its reports of November 1, 1910, and January 23, 1911, has discussed certain of the questions referred to it—namely: I, Feasibility of the waterway; II, the most advisable depths and dimensions for the waterway; III, cooperation with the State of Illinois; IV, conditions necessary in connection with cooperation to fully protect the interests of the United States, and V, plans and estimates of the cost of work recommended to be done by the United States. Since the submission of the above reports nothing has developed to require any changes in the statements and conclusions therein given. For convenience of reference these reports are attached hereto marked as Appendixes E and F.

The necessary additional investigations having been completed, the results of which are shown in Appendixes A, B, C, and D, the board now has the honor to submit the following report upon the remaining questions submitted to it for consideration:

> VI. Such measures as may be required to properly preserve the levels of the Great Lakes and to compensate, so far as practicable, for the diminished level in said Lakes and the connecting waters thereof by reason of any diversion of water from Lake Michigan for the maintenance of the proposed waterway * * * or for any other purpose.

2586 This subject is specially discussed in Appendix A.

Since 1895 the United States Lake Survey, under the direction of the Chief of Engineers, has made a systematic series of measurements of discharges in the St. Mary's, St. Clair, Detroit, Niagara, and St. Lawrence Rivers, to determine the relation which exists between the volumes of water discharged by these rivers and the levels of the lake surfaces. These discharge measurements have been numerous and demonstrate conclusively that there is a direct connection between the height of each lake and the volume of water discharged at its outlet.

For a change of 1 foot from the mean of the stages covered by the observations on each lake the discharge will vary as stated in Table I, and conversely the changes of level in feet, due to diversions from the natural outlets of varying amounts, will be as shown in Table II.

TABLE I.

Lake	Mean stage.*	Discharge at mean stage.	Change in discharge due to 1 foot change in level close to mean stage.
	Feet	Second-feet.	Second-feet.
Superior	601.80	75,000	15,300 gauge at S. W. canal pier.
Michigan-Huron ..	580.38	192,300	21,500 Fort Gratiot gauge. Lake St. Clair normal.
Erie	571.96	195,500	22,300 Buffalo L. H. gauge.
Ontario	244.60	230,000	23,200 Ogdensburg gauge. Discharge adjusted for effect of closure of Gut Channel in Galops Rapids, estimated to reduce existing discharges 9,000 cubic feet per second below those formerly existing at the same stages.

* Mean of range during discharge measurements.

TABLE II.—CHANGES OF LEVEL, IN FEET, DUE TO DIRECT DIVERSION OF AMOUNTS VARYING BETWEEN 1,000 AND 14,000 CUBIC FEET PER SECOND.

1,000 cubic feet	Superior	Michigan and Huron	Erie	Ontario
	Foot	Foot	Foot	Foot
1	0.065	0.046	0.045	0.043
2	.131	.093	.090	.086
3	.196	.139	.134	.129
4	.261	.186	.179	.172
5	.327	.232	.224	.2165
6	.392	.279	.269	.260
7	.457	.325	.314	.303
8	.523	.373	.359	.346
9	.588	.419	.404	.399
10	.654	.465	.448	.431
11	.719	.511	.493	.474
12	.784	.558	.538	.517
13	.850	.602	.583	.560
14	.915	.659	.628	.603

2587 These changes are obscured by variations in the supply of water from rains, by evaporation, by the effects of winds, and by the obstruction of the outlets by ice, and due to the reservoir capacity of the different lakes the action will not be immediate. As shown in the report of the Lake Survey for 1904, page 4120, one-half of the ultimate fall of Lakes Michigan and Huron will occur in 1.46 years, and nine-tenths of the fall will be completed in 4.86 years. For Lake Erie 50 per cent of the ultimate lowering will occur in 2.5 months and 90 per cent in 8 months; for Lake Ontario, in 2.1 months and 7 months, respectively.

It is therefore evident that when the Lakes stand at mean lake level a diversion of 10,000 cubic feet per second from Lake Michigan through the Chicago Drainage Canal will ultimately produce a lowering of the water surface of Lakes Michigan and Huron and its connecting harbors and channels of 0.465 feet (5.58 inches), of Lake Erie of 0.448 feet (5.38 inches), and of Lake Ontario of 0.431 feet (5.16 inches); at lower stages the effect will be greater, due to the relatively smaller area of the cross section of the outlets.

The largest lake freighters recently built carry over 80 short tons of freight for each inch of loaded draft, and an uncompensated Chicago diversion of 10,000 second-feet would cause a loss to each vessel of at least 446

tons in carrying capacity for each down trip through the channels connecting with Lakes Michigan and Huron. This, based upon 25 trips per season, with vessels returning light, means a loss of at least 11,150 tons per year, and at a freight rate of 55 cents per ton represents a monetary loss of at least $6,000 per large vessel per year. During the season of 1912 there passed through the locks at Sault Ste. Marie over 72,000,000 tons of freight, the greater part of which was carried in vessels of such size as to be affected by any loss of depth caused by a Chicago diversion. The tonnage of 1913 bids fair to exceed the tonnage of 1912. The lowest estimate of the loss to American vessels alone that has been brought to the attention of the board is over $1,000,000 per annum, and the loss will increase with the increase in the number and size of vessels.

It is evident therefore that any diversion with consequent lowering of lake levels will cause a direct financial loss to vessel owners and such a loss can be prevented only by the adoption of remedial measures. For this purpose three methods have been proposed. First,
2588 to regulate the level of the Lakes between fixed limits by the construction of submerged weirs and adjustable sluices at the lower ends of the Lakes, and by this means not only to prevent the oscillations of lake levels which occur daily each season, but also to equalize the flow over a series of years. Second, to compensate for the diminished discharge by reducing the area of the natural outlets by construction of contraction works therein. Third, to restore the original depths of the harbors and connecting channels by dredging.

It is the opinion of the board that while it is feasible to raise the average surface of the Lakes to any desired elevation by means of weirs and sluices it will be exceedingly difficult and in many ways impracticable to regulate the oscillations of the Lakes to a greater extent than nature now does automatically. These oscillations arise from winds, from the relative amount of rainfall and evaporation, and from other natural causes, which man can neither control nor forsee. The effect of any attempted regulation will be local rather than general, and the local benefits will be offset by injuries elsewhere. The difficulties in regulating lake levels are fully discussed by the International Waterways Commission in House Document No. 779, Sixty-first Congress, second session, and a resume of the views expressed therein is given in Appendix A.

To restore the diminished levels in the Lakes by constructing contracting works in their outlets does not however present any serious difficulties. A careful discussion of the proper locations and dimensions of such works is also given in Appendix A.

At the foot of Lake Ontario the closure of the Gut channel of the Galops Rapids by the Canadian Government has had the effect of raising the level of Lake Ontario an amount nearly equal to the computed lowering of the lake by a diversion of 10,000 second-feet at Chicago, and no compensation is at present deemed necessary to restore former conditions in this lake.

In Appendix A it is proposed to diminish the outflow of Lake Erie by the construction of three *submerged weirs in Niagara River* in the vicinity of Squaw Island, which would average about 4.2 feet in height and would contain about 15,000 cubic yards of masonry. The estimated cost is $150,000.

To raise the level of Lakes Michigan and Huron *submerged weirs* are proposed *in St. Clair River,* covering 3 miles of river below the mouth of Black River at Port
2589 Huron. The weirs as suggested in Appendix A have a height of from 5 to 6 feet above the river bed, contain about 65,000 cubic yards of material, and their estimated cost is $325,000. It is computed that these weirs will increase the velocity of the water flowing over them slightly (from a mean of 3.28 feet to 3.89 feet per second), but, on the other hand, above the mouth of Black River the river slopes and velocities which are now excessive will be diminished, and navigation on the whole will be considerably benefited.

The Chicago diversion has no effect on Lake Superior.

Compensation for the loss of elevation on Lakes Michigan, Huron, and Erie, and their connecting waters, due to an assumed diversion from Lake Michigan of 10,000 second-feet, will by the plan above outlined involve an expenditure of about $475,000, to which should be added an amount for the maintenance of the weirs, estimated at about $15,000 per year, the total cost being much less than the cost of restoration of depths by dredging. It is the opinion of the board that while other plans have been proposed, compensation by fixed contraction works similar in general to those above described affords the cheapest and most satisfactory method of preserving the levels of the Great Lakes.

No estimates have been considered for compensating for the loss of depths in the St. Lawrence River, as such work is regarded as outside the scope of the duties of the board.

THE SANITARY DISTRICT DIVERSION WORKS COST AND THEIR OPERATION, EFFECTIVENESS, RESULTS, SEWER AND WATER SUPPLY SYSTEM OF CHICAGO AND COST.

George M. Wisner, a witness for the defendant (Rec., Vol. III, p. 1592-1703), January 20, 1914:

Resides at Chicago; civil engineer; graduate U. of Michigan, Academic Department, and also Degree of Civil Engineer, 1892; then Chief Engineer of the Sanitary District of Chicago; been Chief Engineer since 1907; started with Sanitary District in 1892 as a rod-man; then sub-instrument man; then sub-assistant engineer; then assistant engineer; then chief assistant engineer; chief engineer in 1907. As chief engineer, in charge of engineering department; designed all works carried on by the District and constructed and in process of construction; original research by experimental stations, particularly sewage disposal and water purification; duties for Sanitary District in beginning involved studying sewage disposal, sewage conditions, hydraulic problems; in connection with sewage disposal, visited plants at Columbus, Baltimore, Milwaukee, Washington and other American cities, Birmingham, Manchester, London, England; Paris, France and Berlin, Germany.

The witness further testified as follows:

1594 Familiar with all the works of the Sanitary District the sewerage and water supply system of Chicago.

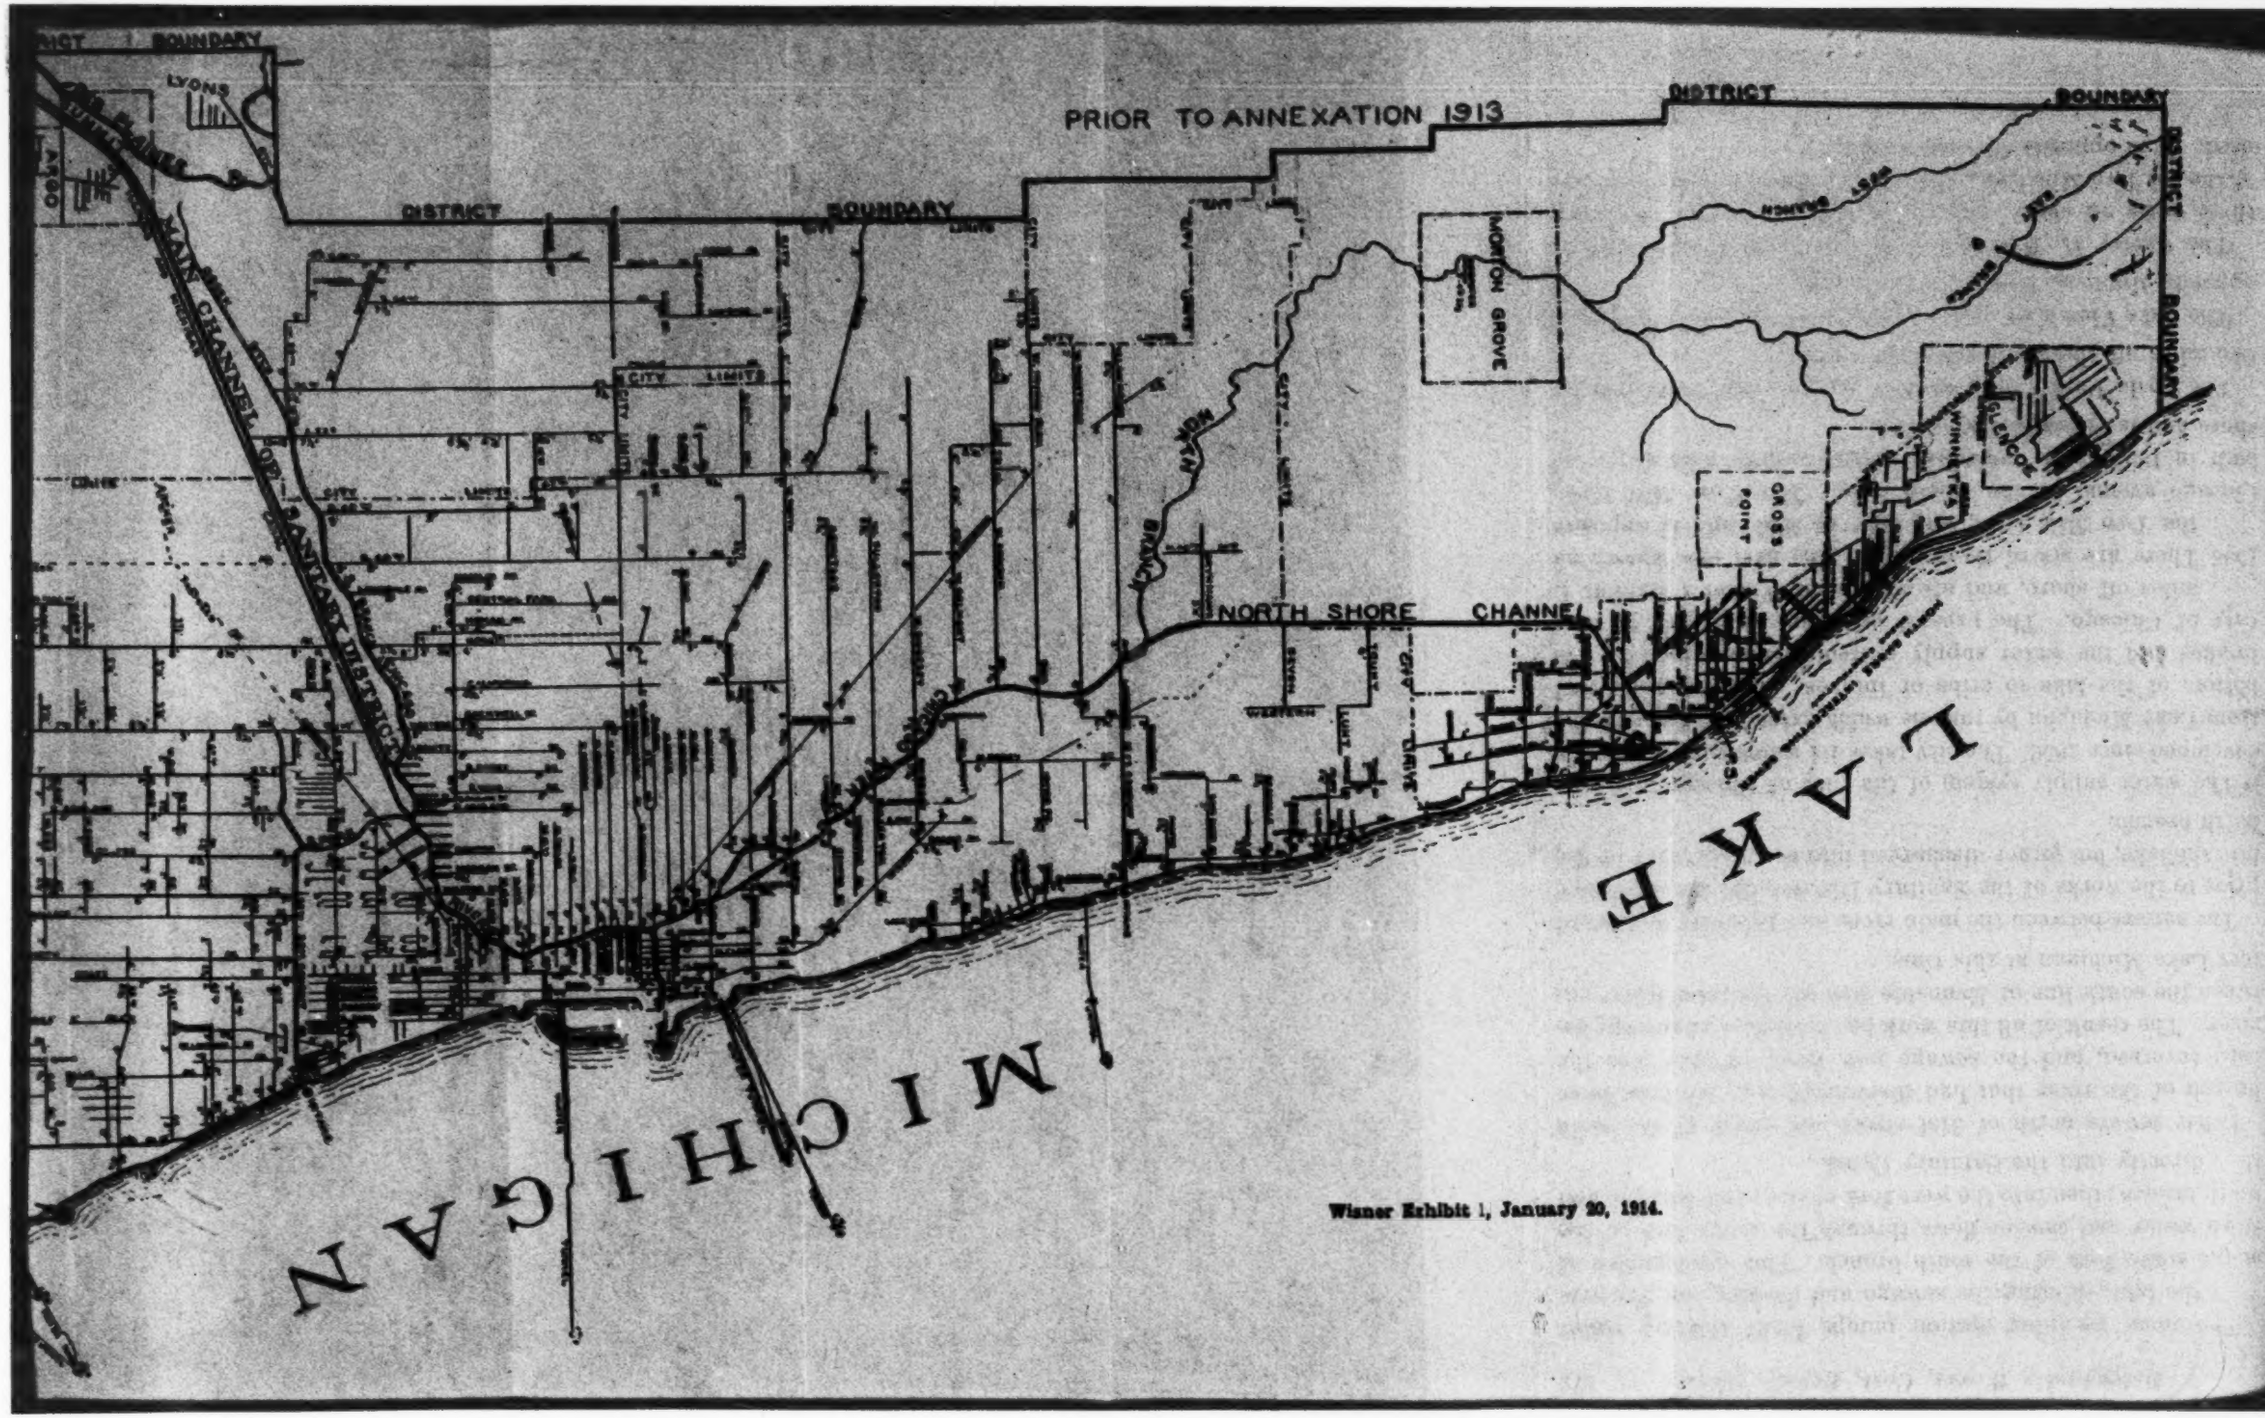
The sewerage system of the City of Chicago consists of sewers built for the collection of sewage; the first one being built in 1855, and they have been added to since, piece by

piece. They range in size from six inch tile up to brick sewers 20 feet in diameter. The more important sewers are those that are two feet in size and over, as shown on Wisner Exhibit 1 on page opposite.

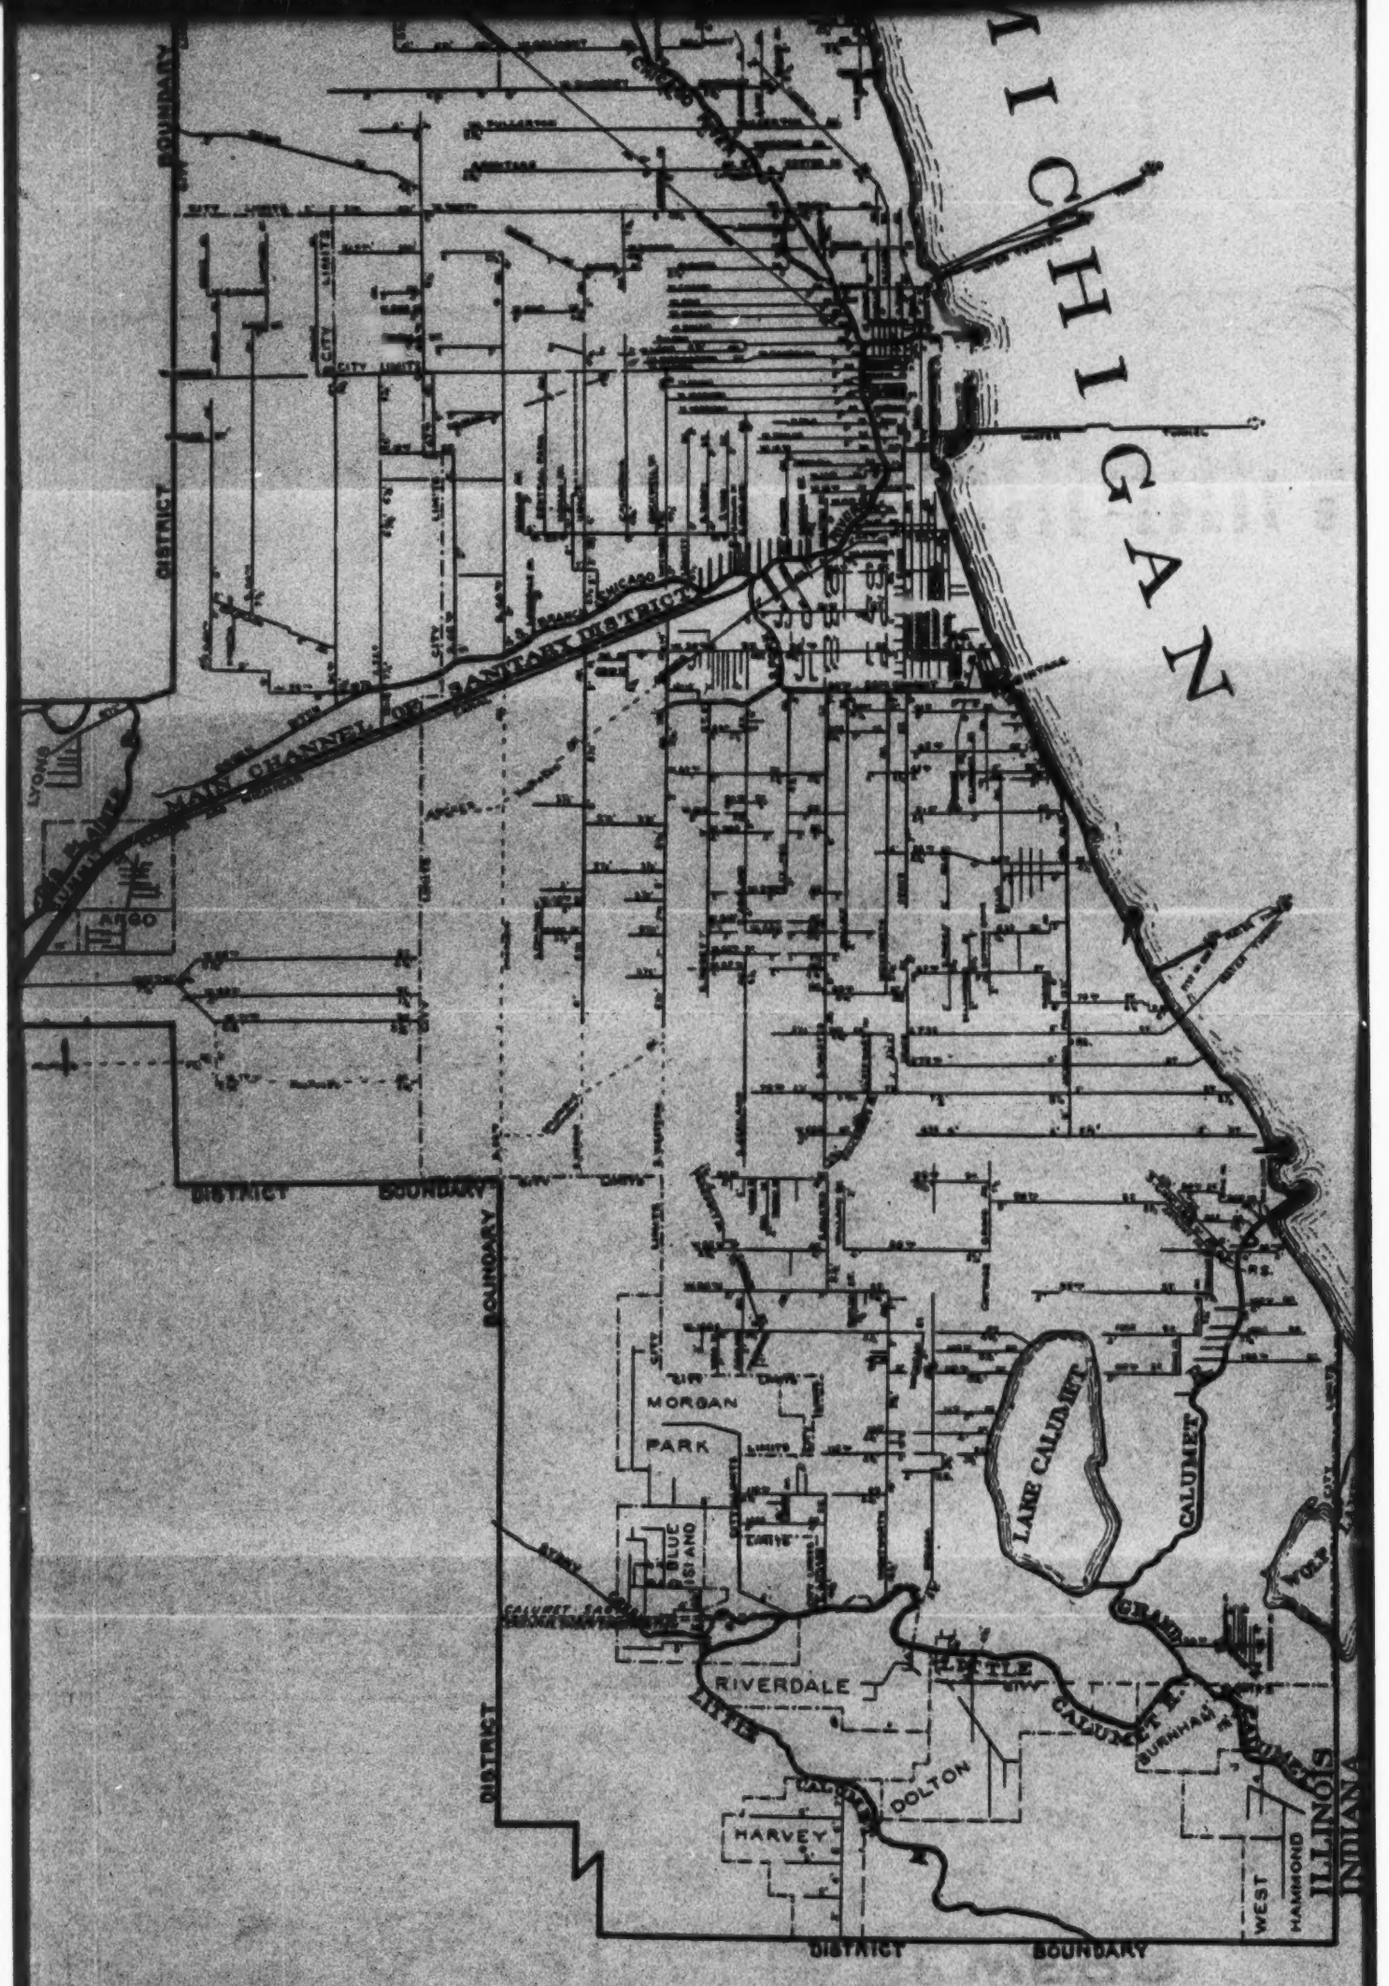
The sewers originally discharged into the Chicago River, and a part of them, on the north and south sides, directly into Lake Michigan. The sewers are all built on what is known as the combined system; that is they receive both the storm water and the sanitary sewage; all the sewage coming directly from the homes and buildings of the city. They also receive to a large extent the manufacturing wastes.

There have been completed recently two main intercepting sewer systems. These were built by the City of Chicago to prevent the sewers that had previously discharged directly into the Lake from discharging into it; in other words to keep the sewage out of the lake. One is on the North Side, and is shown on Wisner Exhibit 1, appearing on page opposite, starting on the north of Howard avenue and running south to Lawrence avenue, and a part of the same system starting on the south at Diversey boulevard and running north to Lawrence avenue, where the sewage is picked up by pumps and forced through a conduit 16 feet in diameter on Lawrence avenue to the west and into the north branch at that street. This pumping station also pumps diluting water
1595 from Lake Michigan, mixing it with the sewage water, and being utilized for dilution of the sewage and flushing the North Branch.

The other intercepting sewer system is on the South Side, as shown on Wisner Exhibit 1, and extends on the south from 87th street north to 39th street and the lake, and from 31st street south to 39th street, preventing the sewage which had flowed directly into the lake from flowing therein. At 39th street it is picked up by pumps and forced through a 20-foot conduit west to Halsted street, where it discharges into the east arm of the south fork of the south branch of the Chicago River. This is the arm of the river that is commonly known as Bubbly Creek. (Wisner Exhibit 1, inserted on page opposite.)



Wisner Exhibit 1, January 20, 1914.



SANITARY DISTRICT OF CHICAGO

MAP OF THE

CITY OF CHICAGO AND VICINITY

SHOWING

MAIN OUTFALL SEWERS.

CHICAGO JANUARY, 1914.

SCALE IN STATUTE MILES

The same pumping station pumps fresh diluting water from the lake, diluting the sewage and flushing out the arm of the south fork of the south branch. This combination of fresh water and sewage flows through the south fork to the south branch; then into the west fork of the south branch, and thence directly into the Sanitary Canal.

Other sewers north of 31st street and south of the main branch of the river that had discharged into the lake have been reversed, and the sewage now flows directly into the river. The result of all this work has been that no sewage between the south line of Evanston and the Calumet River enters Lake Michigan at this time.

The sewers between the main river and Diversey boulevard prior to the works of the Sanitary District, did not discharge into the lake, but either discharged into the main river or the north branch.

The water supply system of the City of Chicago has been developed since 1852. The city takes its water supply directly from Lake Michigan by tunnels which extend out beneath the bottom of the lake to cribs or intakes. These tunnels and intakes and the water supply system is maintained by the City of Chicago. The present cribs are from two to four miles off shore, and are shown on Wisner's Exhibit 1.
1596 There are six of these cribs. The first one, known as the Two Mile Crib, was built in 1867, and is opposite Chicago avenue on the North Side. The Four Mile Crib, built in 1892, is, as indicated, approximately four miles off shore and is opposite 14th street.

The Hyde Park Crib was built in 1894, and is practically two miles off shore opposite 68th street.

The Lake View Crib built in 1896, is two miles off shore and opposite Montrose avenue, or boulevard.

The Carter H. Harrison Crib was built in 1899, and is three miles off shore; practically amounts to the extending of the old Two Mile Crib, although I believe at times both are used. It is opposite Chicago avenue.

The Dunne Crib built in 1910, is two miles off shore and opposite 68th street. It is right alongside of what is known as the Hyde Park Crib. It was put in to give additional capacity for this particular part of Chicago that those two cribs serve.

This water, after passing through these tunnels under the lake is then carried by land tunnels to pumping stations located in different parts of the city, and forced through the mains to consumers.

The Sanitary District was organized in 1889, and the construction was started in 1892. The principal feature of its work has been the construction of what is known as the Main Channel. This channel begins at Robey street and the Chicago River, which is about 6 1/3 miles from the mouth of the river. It was originally 28.05 miles long and extended from Robey street the starting point to Lockport, Illinois. Practically the first 14 miles of it was through clay and glacial deposits, and the lower 14 miles was through limestone rock.

The Chicago end of the canal, for about 7 miles, was constructed to about half of the ultimate capacity. It was capable of progressive development as the needs for additional water became necessary to dilute the sewage. This extended to a place known as Summit.

1597 From Summit to Willow Springs, a distance of another 7 miles, the channel was constructed to its full capacity; and from Willow Springs to Lockport, through the rock, it was constructed to its full capacity.

The channel at the upper end was 110 feet wide on the bottom, and had side slopes of one vertical on two horizontals.

The second stretch through the glacial deposit to Willow Springs was 202 feet wide on the bottom, and with the same side slopes. From Willow Springs to Lockport, generally, the channel was 160 feet wide on the bottom, and 162 feet wide on the top, with sides that were practically vertical.

At the end of the channel were controlling works for regulating the amount of water flowed through the Chicago River and the Main Channel.

In 1903, the right was obtained from the Legislature to develop power which had been incidentally created in connection with this work, and the channel was extended to practically the City of Joliet. Prior to this, however, the Sanitary District had done considerable work improving the Des Plaines River below the end of the Main Channel and through the City of Joliet, removing several dams nd deepening the stream, building levees and walls. This power development involved the lengthening of the upper reach of the Main Channel for about two miles, at which point was located a power house, dams for regulating the flow and a lock for the passage of vessels from one level to the lower level. It developed an average head of about 34 feet, and the plant is capable of developing about 4,000 kilowatts for every 100,000 cubic feet of water flowed per minute; generally, in round numbers, that is true.

Below the power house, the channel is carried on the same depth, practically the same depth as above the power house, which I neglected to give, it being about 24 feet at normal stages of the lake, to a point near to the upper limits of Joliet, where it is from there through the City of Joliet ten feet or over in depth. This power extension was completed in the latter part of 1907.

This work involved the construction of transmission lines and distributing systems in the City of Chicago, most of the power being brought to Chicago for the lighting
1598 of streets and pumping of water for the municipality, the excess being sold for commercial purposes. This power was all developed incidental to the sewage disposal, and the District has never flowed more water on account of power developments than it would have flowed if there had been no development there. Prior to this construction this power was simply going to waste, and it simply amounted to the conservation of this wasted energy.

In connection with getting water through the Main Channel, it became necessary, on account of the restrictions placed

on the velocity of the current in the South Branch for the Sanitary District to improve the South Branch of the Chicago River by widening and deepening it and by the removal of certain bridges, whose center piers interfered with the free passage of the water through the river.

The Sanitary District has expended approximately $11,500,000, on the improvement of the Chicago River. This money was expended almost entirely under what is known as the 1900 Project. It generally was expended to widen the South Branch from its junction with the North Branch at Lake street to the beginning of the Drainage Canal at Robey street. The river has been widened to a width of at least 200 feet, and it has been deepened so that at the dock lines there is a depth of water of 16 feet, gradually deepening to a point 50 feet out from the docks where it is 26 feet deep for the middle 100 feet of the river. This depth of water is below what was known as the hydraulic grade of the river; that is the water in flowing from the Lake to the Drainage Canal has a slope which at times is two feet lower at Robey street than the Lake level.

This widening of the Chicago River involved the purchase of over 792,000 square feet of property along the Chicago River, and generally, I should say, the river had been widened on an average 50 feet. The widest piece taken off was 110 feet in width, and from that down to nothing.

This involved the excavation of over 5,500,000 cubic yards of material; the construction of over 19,000 lineal feet of dock, for wherever the Sanitary District widened the river it became necessary to build new docks.

In the improvement of the river, as already stated, the Sanitary District replaced many of the old center pier bridges with bridges of the modern type, known as bascule 1599 bridges. It has replaced or rebuilt the following bridges across the Chicago River: State street, Dearborn street, Randolph street (and is now engaged upon the construction of a new bridge at Jackson boulevard), Harrison street (Polk

street was built by the City of Chicago), Taylor street, Chicago Terminal Transfer Railroad Bridge, now owned and operated by the Baltimore & Ohio Railroad (it has agreed to pay half the cost of rebuilding the 12th street bridge, which has been ordered out by the Secretary of War), 18th street, Canal street, 22nd street, Main street, Throop street and Ashland avenue. One other bridge was removed and reconstructed by the City of Chicago. That is at Washington street.

Widening the river also involved the removal of many buildings, and paying damages to adjacent property owners.

The Sanitary District has also widened and deepened the North Branch of the Chicago River from Belmont avenue to Lawrence avenue, a distance of about two miles. This stream, prior to this straightening and deepening, was practically dry in the summer time, simply being a small creek. The Sanitary District made a stream having a depth of 12 feet and a width of 90; and has also deepened the South Fork of the South Branch to a depth of 20 feet; has done considerable work in the West Fork of the South Branch west of the beginning of the Main Channel, deepening it about three feet.

This, generally, covers the work done by the Sanitary District as far as its main channel and the Chicago River are concerned, with the possible exception of the North Shore Channel which was completed in the latter part of 1910 and early in 1911; and it extends from Wilmette and the Lake to the North Branch of the Chicago River at Lawrence avenue. This was a rather small canal, having about 13 feet of water. It is navigable and was built to take care of the sewage coming from what is known as the North Shore towns, that is the towns from Glencoe south to the Chicago Limit, including Evanston, Wilmette, Winnetka, Kenilworth and Glencoe. It is provided with a pumping plant at Wilmette, which pumps 1,000 cubic feet of water per second through this canal and down into the North Branch, and the water to be used for diluting the sewage and flushing out the North Branch, which otherwise would be stagnant, septic, and become a local nui-

sance. This water flows then directly into the South Branch and into the Drainage Canal.

The South Branch had been dredged by the United States Government to a depth of 17 feet, but it had shoaled up
1600 considerably, due to silt coming in from the lake and sediment coming from sewers, so that at the time the District started on the deepening of the South Branch, it did not have available probably over 16 feet.

At Joliet, the terminus of the Sanitary District Channel there was space left, and the work was so designed that a large lock could be installed when the deep waterway is constructed.

The Chicago River through the main river is 20 feet; through the South Branch and West Fork down to the main channel 26 feet. The main channel itself at ordinary stages is at least 24 feet as far as the power plant. Below the power plant it is 20 feet to the north limits of Joliet, and from there on at least 10 feet in depth down to Dam Number 1, which is near the center or heart of the city of Joliet. Below there the Des Plaines River is not navigable. The only means of navigation from there on at the present time to the Illinois River is by way of the old Illinois and Michigan Canal.

The United States has expended in the improvement of the harbor at the mouth of the Chicago River approximately $2,390,000. No part of that sum was expended in the improvement of the Chicago River. The Government did not expend any money in connection with the improvement of the Chicago River until 1896.

Since 1896 the United States expended, up to say June 30, 1913, in the improvement of the Chicago River itself approximately $1,626,000.

It was expended for dredging the North and the South Branches to a depth of 17 feet on the first project, and later the deepening of the North Branch as far north as Belmont avenue, I think, to a depth of 20 feet.

The Government also bought some land on both branches of the river for the purpose of constructing what is
1601 known as turning basins. These are basins that are large enough so that vessels can turn around and come back down the river bow first. The one on the North Branch is at Diversey boulevard, and the one on the South Branch is at the junction of the West Fork and the South Branch, just east of Ashland avenue. Part of this money on the original project was expended for widening the Chicago River at some of the narrowest and most dangerous places. Part of this money was expended deepening the main branch of the river to a depth of 20 feet from the mouth to the junction of the two branches. Generally this covers the money that was expended by the Government for the improvement of the river.

The City of Chicago has expended in the improvement of the Chicago River approximately $6,275,000.

From about 1861 to the present time, approximately to this time it was expended for dredging of the Chicago River, both the main river and on all its branches, building of bridges and docks, and general improvements.

These improvements in the Chicago River were done by the United States Government during the time that the Sanitary District was completing its works—particularly the South Branch. The deepening of the North Branch has been done in quite recent years; that is deepening the North Branch to 20 feet.

Since the 17 foot project of the United States Government it has done no work on the South Branch, although it has deepened the North Branch to 20 feet. The Sanitary District took up its work and did this dredging. When the Sanitary District started on this project, the Government had not quite completed the dredging to 17 feet. It was widening the river at certain places where it was narrow, that is the South Branch. Some of this work of the Government and the Sanitary District was carried on simultaneously. The widening

done by the Government however was at a few places, and did not amount to very much.

The Sanitary District commenced its work on the improvement of the Chicago River along about 1896.

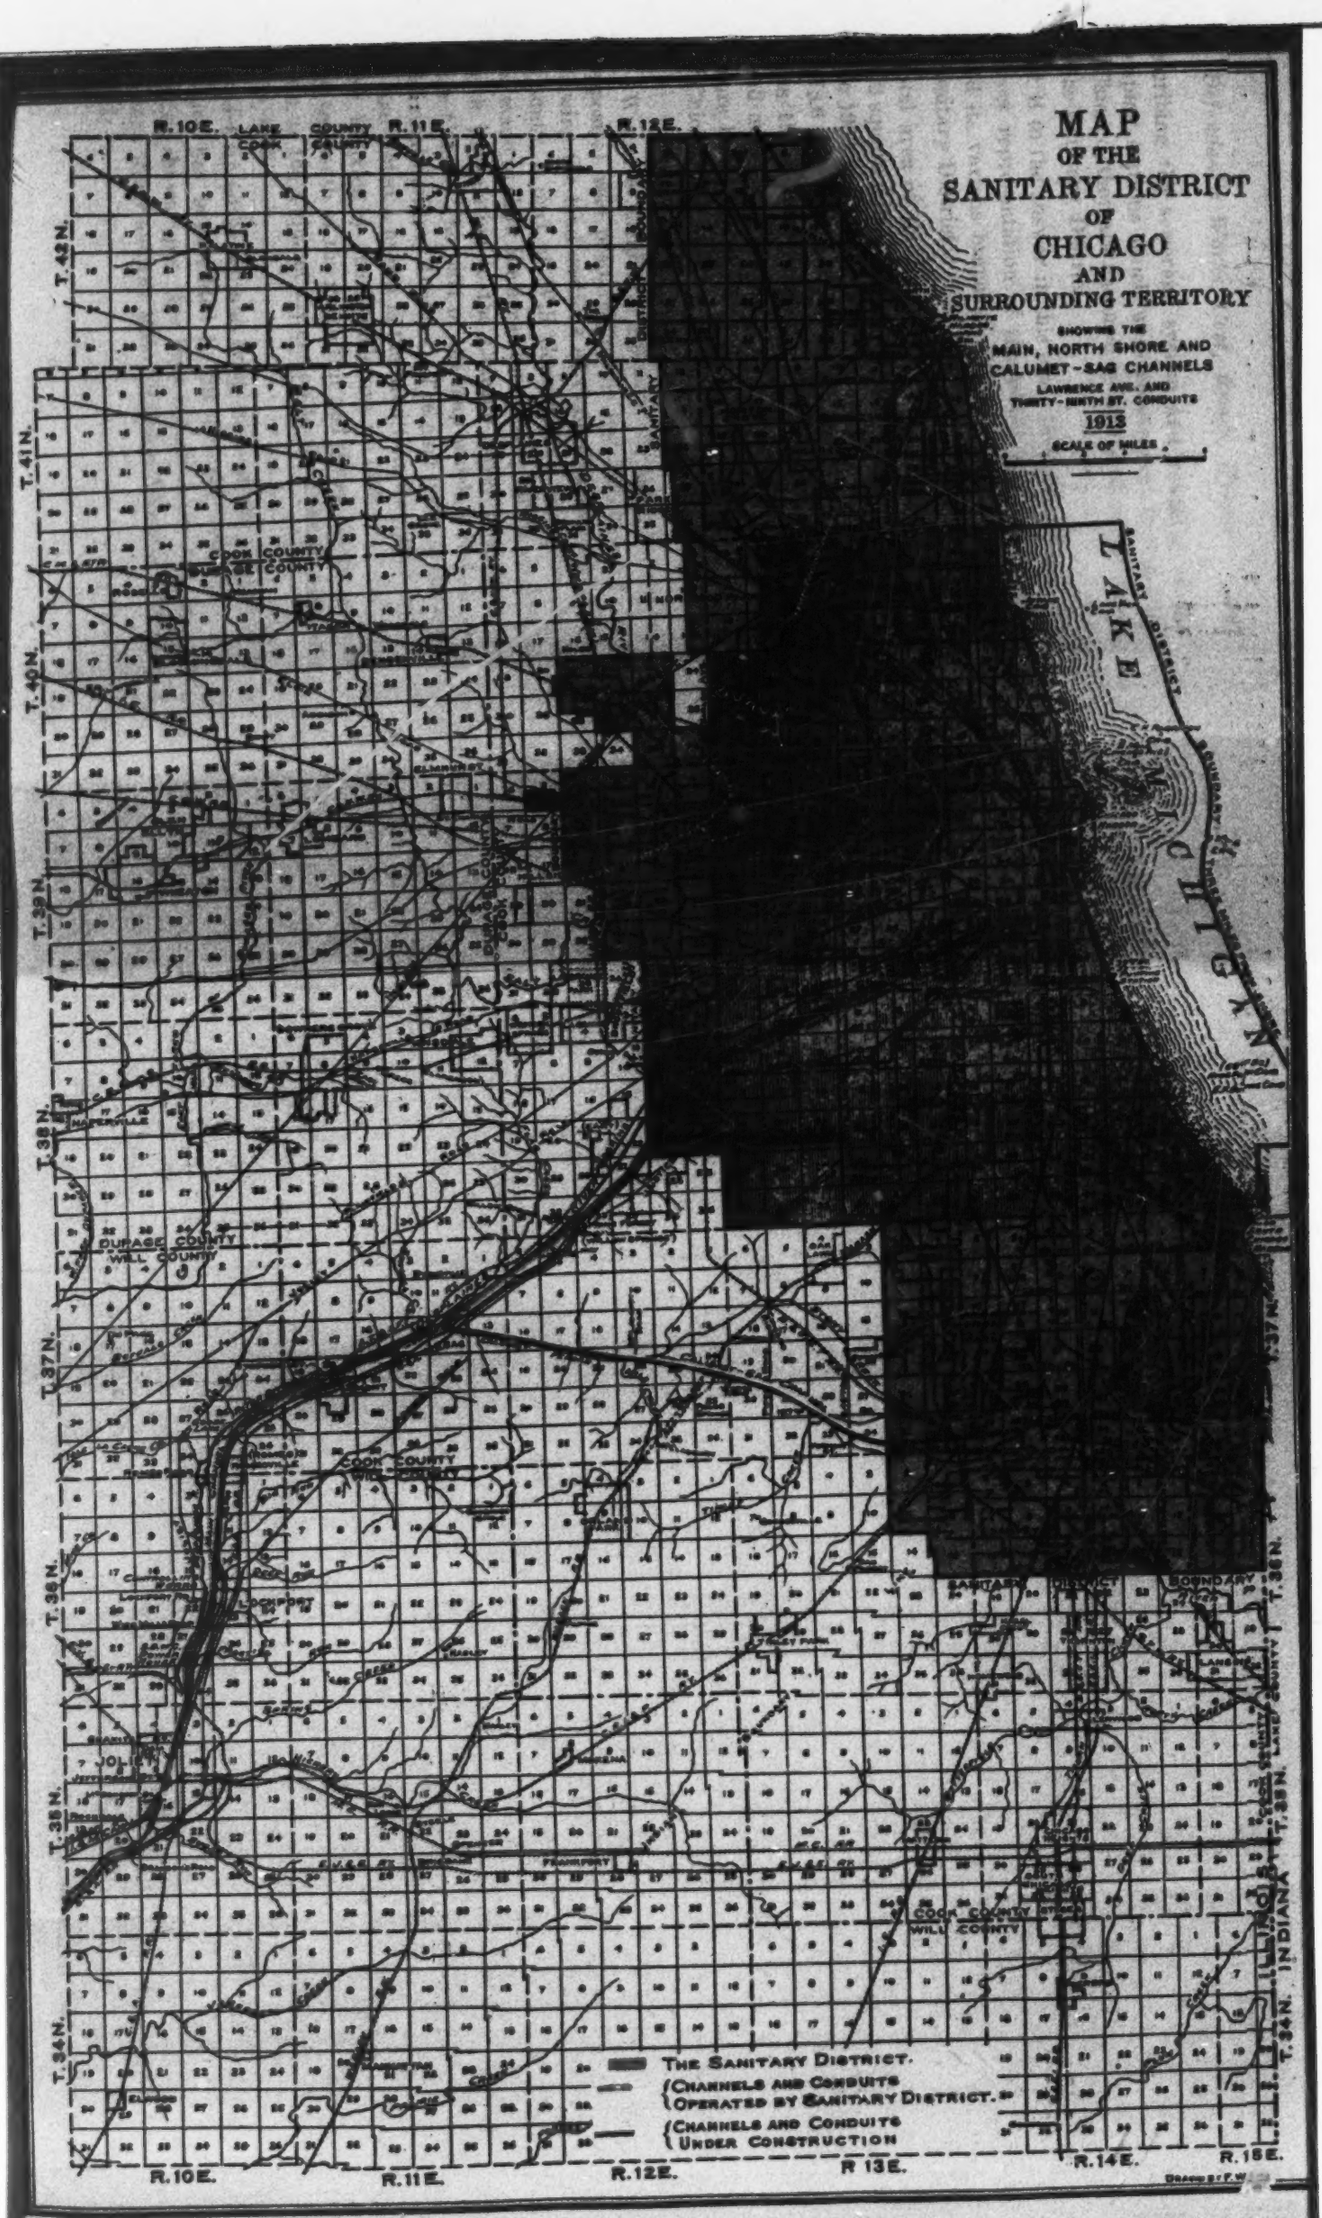
1602 Prior to the time the Sanitary District widened and deepened it, boats drawing over 16 feet of water could not have navigated the South Branch, even providing that the tunnels had been removed, for the reason that there was not any more available depth than that. Up to the time that the Sanitary District started its dredging a boat over 400 feet in length could not have navigated beyond 22nd street, for the reason that between 22nd and Halsted street the river was very narrow and tortuous, and a boat of that length could not make the turn. Boats having a beam greater than 48 feet would probably not have been able to pass through some of the bridge openings. These bridges have since been removed and replaced by modern bridges giving a wider opening.

As the result of the Sanitary District improvements in the Chicago River at this time a boat of probably 500 feet could navigate the river, and drawing 20 feet; the depth being controlled by the depth of the main branch of the river. If certain bridges, which are now either coming out or shortly to come out are removed, a boat of larger length could be taken down the river.

In the South Branch the critical point probably, the critical stretch, is from Lake street to the turning basin at Ashland avenue. This will safely take, in my opinion, 8,000 cubic feet a second. From there on to the Drainage Canal, the river is much wider, and with the same depth would take an additional flow of water without any injury to navigation.

The current would not exceed 1¼ miles an hour through that stretch anywhere.

The Sanitary District has done some work in improvement on the Illinois River, and some improvement in a sanitary way for some of the smaller towns within the limits of the Sanitary District.



ORIGINAL SANITARY DISTRICT SHOWN IN GREEN.

In describing the sewerage system and speaking of the pumping stations which were constructed by the City
1603 of Chicago, they are assumed to be a part of the works of the Sanitary District.

Exhibit B to the answer in this case (this narrative p. 79) is a correct representation of the position of the Chicago River and its various branches with reference to the limits of the Sanitary District.

The total area of the Sanitary District is at the present time 386.2 square miles. The original Sanitary District, that was up to 1903, was 185 square miles. The North Shore District of 78.6 miles was added at that time, as was what was known as the Calumet District amounting to 94.5 square miles, and under a recent act of the Legislature 28.1 square miles more have been added to it. This includes all of the City of Chicago, the area of which is a little over 191 square miles.

Map (Wisner's Exhibit 2, January 20, 1914, inserted on page opposite) was prepared under my direction. It is a map showing the land sections of Cook County, part of Du Page County, a part of Will County; and generally shows and was made to show the areas comprising the Sanitary District with its relation to the Chicago River and the main Drainage Canal. The part of the map which is tinted green is the original Sanitary District. The part lying to the north of this and tinted a brown is the area that was added to the Sanitary District by the Legislature in 1903; and the part lying to the south of the green tint and tinted brown is what is known as the Calumet Extension to the District, and was added in 1903.

The part tinted brown and lying west of the green tint is that which has been added to the District recently. The yellow tint shown upon this map indicates the branches of the Chicago River and the Main Drainage Channel extending to Joliet.

1604 The part tinted red, or red line, and marked Calumet-Sag Channel is the Calumet-Sag Channel which is now being constructed from the Little Calumet River, east of Blue Island to the present main drainage channel at the place marked Sag.

The Fullerton avenue conduit was built by the City of Chicago prior to the Sanitary District work, and is a conduit extending from Lake Michigan to Fullerton avenue and the North Branch; was installed for the purpose of flushing the North Branch.

The Calumet Sag Channel is a channel extending from the Little Calumet River just east of Blue Island to the Main Drainage Channel at the Sag, a distance of approximately 18 miles. It is a channel which is to have water 20 feet in depth, and through the rock sections is 60 feet in width, and through the earth sections generally 36 feet in width on the bottom, with side slopes varying from one vertical to two horizontal, to flatter slopes.

It is to have regulating and controlling works located at its eastern end, which will control the amount of water that can flow through it. Generally it is designed to carry 2,000 cubic feet per second at this time, but it is capable of progressive development so that it can ultimately be enlarged to carry at least 4,000 cubic feet per second. It was not done at this time for the reason that it figured cheaper to make this progressive development than to make a large initial investment, which would not be needed for some years to come.

At the present time, this work is under construction, there being nine contract sections awarded by contract averaging about a mile and a quarter long; there are about five more to be let within the next few months.

This canal will be navigable.

Cities, villages and towns located within the limits of the Sanitary District are Chicago, Evanston, Glencoe, Winnetka, Wilmette, Shermerville, Glen View, Morton Grove, Niles, Cicero, Stickney, Evergreen Park, Morgan Park, Blue

1605 Island, Riverdale, Oak Park, Berwyn, Forest Park, River Forest, Maywood, Riverside, Brookfield, Bellwood, Franklin Park, Melrose Park, River Grove, Dolton, Harvey, West Hammond, Worth, Bremen, Calumet, Kenilworth, Burnham.

The drainage area of the Chicago River basin is about 307 square miles. The run-off of the Chicago River basin in a dry season is practically the city water supply, and some little ground water, but at times of maximum floods it will reach as high as 10,000 cubic feet per second.

The inhabitants of the Sanitary District within the boundary of the Sanitary District have generally no available water supply other than Lake Michigan.

It would be impossible to supply the entire inhabitants of the Sanitary District with a good supply of water by any other means. There are a few wells in Chicago and the smaller places, which are used for that purpose; but it would be impossible to get sufficient water from a ground supply to supply the entire city.

Prior to the opening of the Drainage Channel to illustrate what the appearance of the Chicago River was, it is only necessary to say that practically the entire North and South branches were in the same condition as that part of the Chicago River known as Bubbly Creek is at the present time. It was a filthy, dirty sewage polluted water, in a septic condition, with gas bubbles rising; having large cakes of floating sewage mud. This mud was held at the surface by the gas being generated in it. A large percentage of the docks along the river were falling into the stream. The river was littered up with old worn out bridge protections which interfered with the passage of boats, and in fact often proved a menace to the boats, for the reason that the piles were rotted off below the surface of the water. Not only the appearance of the river was objectionable to the eye but the odors coming from it were objectionable to the nostrils; and at times of flood could be smelled for long distances. It was a disgrace to a civilized community at that time.

At times it flowed in different directions. The current was practically stagnant except in times of floods due
1606 to heavy rains, and the run-off of melting snows. Although the Bridgeport Pumping Works were operating, pumping between 40,000 and 50,000 cubic feet of water per minute out of the South Branch, this was so insufficient that it did not make any perceptible current; and often the current could be observed running towards the lake, due to the sudden drop of the lake level.

When the lake would rise, one might observe a current of water coming in from the lake, but generally the river was stagnant.

In times of heavy rains, this sewage polluted water was driven by the storm run-off into the lake, polluting the water supply. This was traced to several miles from shore, and went even beyond the present location of the Four Mile Crib.

On account of the lake rising and falling as stated above, large quantities of this sewage polluted water found its way into the lake and resulted in not only the river itself being objectionable to the eye and nose, but the lake at the mouth of the river was objectionable. It contained large quantities of sewage pollution for a considerable distance from the mouth of the river.

The opening of the Drainage Channel absolutely remedied this condition, so that at the present time there is no local nuisance in the Chicago River and the sewage does not get into the lake polluting the water supply at any place between the Calumet River and the south line of Evanston.

Up to December 31, 1912, $61,845,838 had been expended by the Sanitary District of Chicago and the City of Chicago for the construction of works now in operation. The works of the Sanitary District of Chicago include the Main Channel, North Shore Channel, and the various appurtenances necessitated, including bridges, the enlargement of the Chicago River, the diversion of the Des Plaines River, and the construction of flushing pumps. Those paid for by the City

1607 of Chicago include the intercepting sewers on the North and South Sides, the Lawrence avenue sewage pumping station, and also the sewage pumping station at Fullerton avenue and 39th street. The Sanitary District, as stated before, paid part of the construction of the 39th street station.

The 39th street pumping station and conduit, in taking water away from Lake Michigan has a capacity of 2,000 cubic feet per second, or 120,000 cubic feet per minute.

The Lawrence avenue pumping station has a capacity of 40,000 cubic feet per minute.

It is the intention to flow 8,000 cubic feet per second through the main river and the south branch to its junction with the South Fork of the South Branch, at which place will come an additional 2,000 feet from the 39th street pumping station, and from this junction of these two branches to the Main Channel, a flow of 10,000 cubic feet.

As stated before, this stretch of the river is wider than the river is east and north of Ashland avenue, and is fully capable of taking the 10,000 feet without creating a velocity of probably over a mile an hour.

The cost of the works built and paid for by the Sanitary District of Chicago and the City of Chicago, for the purposes of sanitation, with a rated capacity of 10,000 cubic feet per second through the Main Channel, and having a velocity in the Chicago River not to exceed a mile and a quarter per hour is $64,095,000.

This cost is made up of the amount expended by the Sanitary District on completed works, which has already been mentioned, and the expenditure by the City of Chicago for works already described, and for the work which has been practically finished during the last year, which is the widening of the eastern end of the present Main Channel, which have been spoken of before as being capable of progressive development; and also includes an estimate of the cost of completing the Chicago River widening to 200 feet. There yet remains four places where it is not quite com-

pleted; and certain other minor details, which go to bring this figure up to the amount stated.

1608 These costs have been taken from the books of the District and the City of Chicago. An allowance has been made for the actual interest on the bonds prior to the opening of the Main Channel in 1900, an estimated amount for interest during construction for works built by the District after 1900, and a proportion of the overhead charges of the District pro rated in accordance with the construction and maintenance expenditures. An allowance has also been made for the interest during construction on the city expenditures.

The following table gives in some detail the money that has been expended for different purposes and projects.

COST OF WORKS OF THE SANITARY DISTRICT OF CHICAGO AND THE CITY OF CHICAGO.

The Sanitary District of Chicago— To December 31, 1912.	
Right of Way,	$9,703,018.37
Construction of Main Channel and Controlling Works,	19,813,197.96
Bridges (Incl. Chicago R., North Branch and North Shore)	6,633,073.23
North Shore Channel and Wilmette P. Sta.	1,450,985.83
Rivers (Chicago River, River Diversion, and North Branch)	3,666,720.23
Flushing and sewers,	782,150.20
Joliet (Joliet Project, incl. bridges)	1,601,104.30
Administration, Engineering, Legal and Clerical Expenses (Excluding water power eng., and Calumet Sag and prorated M. & O. charge)	6,658,923.05

Miscellaneous (Illinois and Michigan Canal)	167,404.88	
Bond interest and Premium Acct. to Dec. 31, 1899, actual,	2,950,618.42	
Interest computed on construction carried on from Jan. 1, 1900, to Dec. 31, 1912, allowing equivalent one year at 4¼ per cent	737,697.42	
1609 Damages, Lands, Marine, personal	276,782.11	$54,441,676.00
Contract Work in 1913 and 1914.		
Estimated Overhead Expense	900,000.00	
Estimated Cost of Dredging	1,486,085.00	
Interest during construction 1 year at 4¼%	63,158.61	$ 2,249,243.61
	(Exhibit Cont.)	
	For	$56,690,919.61
The City of Chicago—		
Intercepting Sewers, Land, etc.	$5,312,024.74	
Fullerton Ave. Pumping Station	115,308.75	
Lawrence Ave. Pumping Station	452,635.65	
39th Street Pumping Station	944,143.98	
Estimated Interest during Construction — half period on four year basis	580,049.62	$ 7,404,162.74
		$64,095,082.35

The annual cost of the works for a diversion of 10,000 cubic feet per second is $508,832.09, including maintenance and operation, overhead charges and depreciation; and an allowance has been made for the receipts from rental.

This brings the total cost of a 10,000 cubic feet diversion project up to $76,067,582. This sum includes the annual cost

capitalized at 4¼ per cent and the original construction investment. The details are as follows:

M. & O. acct. 8,000 c. f. p. s.	$	210,036.99
1610 Estimated overhead		50,032.33
Depreciation:		
Main Channel, etc., as of 8,000 c. f. p. s.		265,030.68
Addit. investment ½ of 1% on $2,249,243.61		11,246.22
City Acct.		
½ of 1% on 6,414,440.88		32,072.20
5% on 409,672.24		20,483.61
	$	588,902.03
Less rentals		80,069.94
Annual		508,832.09
Capitalized at 4¼%		11,972,500.00
Investment		64,095,082.00
Corrected figures		$76,067,582.00

To December 31, 1913, about $2,080,000 has been expended on the Calumet-Sag Channel. This includes the construction of the channel, purchase of right of way, engineering, legal and real estate expenses; but no allowance for overhead or interest upon the money invested. The additional liability incurred on account of contracts that have been awarded is about $3,300,000. This brings the total amount of the liabilities up to about $5,380,000.

The estimated cost of the completed project is $14,290,000. This is made up of the items as given in the following table. This includes the construction of the channel for a capacity of 2,000 cubic feet per second, with controlling works, intercepting sewers to bring the sewage to the channel from the principal centers and for the sterilization of certain storm overflows, land, engineering and contingencies.

1611 CALUMET SAG CHANNEL

2000 C. F. P. S.

Canal Proper, incl. Eng. & Con.		$ 8,140,435.00
Contingencies 10%		814,043.00
Interest during Constr.—		
Allow for three years at 4¼% on	$8,954,478.00	1,141,695.00
Old Accounts—		
Main Channel Extension	458,082.50	
Bridges	179.08	
Engineering Expense	32,969.69	491,231.27
Interest on $491,231.27 1 year at 4¼%		20,877.33
		$10,608,282.53
Intercepting Sewer (1930) at 900 gals. P. Cap.	$1,468,045.00	
Pumping Stations (Bldgs. 1930 Eq. 1920	617,025.00	
Disinfection Plants	489,054.00	
Sewers account West Hammond, Harvey and Hegewisch	177,214.00	
Land	100,850.00	
	$2,852,188.00	
Eng. & Conting. 15%	427,828.00	
	$3,280,016.00	
Inter. during Constr.—		
Allow 3 years at 4¼%	401,802.00	3,681,818.00
Total cost		$14,290,100.53
Capitalized operating cost of Channel, etc		1,424,500.00
Capitalized operating cost sewers, etc., as of 1920		3,734,870.00
Total, Capitalized and Construction		$19,449,470.00

The capitalized operating cost of the channel is $1,424,500, and of the sewers that are to be constructed in connection with it $3,734,870, bringing the total capitalized cost and construction cost up to $19,450,000 in round numbers.

1612 The construction cost of the Calumet-Sag Project for a diversion of 4,000 cubic feet per second is estimated to bring the total construction cost of this channel when enlarged to 4,000 cubic feet per second up to $19,925,000. The capitalized operating cost would be, $6,229,000. The total capitalized cost and construction cost will be $25,729,000, in round numbers. The following is an estimate in detail, giving these figures:

CALUMET-SAG CHANNEL.

4000 C. F. P. S.

Cost of 2000 C. F. P. S. project,		$14,290,100.00
Additional to widen channel,		5,000,000.00
Interest during Constr., say 2 years at 4¼% ($200,000) (12,500)		425,000.00
Additional to bring equipment Pump Sta., etc., up to 1930.		
Pumping Sta.	$ 75,000.00	
Miscellaneous sewers, etc.	135,000.00	210,000.00
Total Construction Cost,		19,925,100.00
Capitalized Operating Cost (as of 1930)		
Total for sewer,		4,216,800.00
Total for channel,		2,012,740.00
Total Capitalized and Construction cost,		$25,729,640.00

The capacity of the Main Channel from the terminus of the Calumet-Sag Channel to the controlling works is 14,000 cubic feet per second.

The following is a table giving the costs for the different 1613 flows:

Flow Cu. Ft. Per Sec.	Investment of Construction cost	Annual Cost Operating Plus Depreciation	Capitalized Gross Cost
10,000	$64,095,082.00	$508,832.00	$76,067,600.00
+2,000	+14,290,100.00	+219,273.00	+19,449,470.00
12,000	78,385,182.00	728,105.00	95,517,070.00
+2,000	+5,635,000.00	+58,133.00	+7,002,840.00
14,000	84,020,182.00	786,238.00	102,519,910.00

The cost of the electrical development of the Sanitary District to December 31, 1912, was $5,349,241.57. This comprises the book account valuation of the electrical development of $5,047,625.57, plus an allowance made to have this cost comparable with the other costs for the purpose of our analysis, the allowance covering interest during construction, taken at 4¼% on the cost during construction for ½ the period during which these works were being built.

The following table gives the investment cost on the construction, the annual cost of operation and the gross capitalized and construction cost and the capitalized electrical credit; and this is subtracted in the last column from the gross capitalized cost. The allowance for the income coming from the electrical department is based on the value in the Chicago market for electric energy used for commercial purposes; and is based on what could be developed over that which could be developed with a flow of 4,167 cubic feet per second.

The present electrical plant and equipment is sufficient to generate the energy coming from the flow of 14,000 cubic feet per second, with the possible exception that one electrical water wheel unit would have to be installed, provision for which has been made.

1614 NET CAPITALIZED COST DILUTION SCHEME.

Flow Cu. Ft. per Sec.	Investment or Construction	Annual Cost Operating Plus Depreciation	Capitalized Gross Cost	Electrical Credit Capitalized	Net Capitalized
10,000	$64,095,082.00	$508,852.00	$76,067,600.00	$13,242,000	$62,825,600
12,000	78,385,182.00	728,105.00	95,517,070.00	17,790,000	77,720,970
14,000	84,020,182.00	786,238.00	102,519,910.00	22,306,000	80,213,900

Since the sewerage system was started to be installed in 1855, the City of Chicago has expended, up to December 31, 1912, $31,867,268.68. This is exclusive of any intercepting sewers. The sewer systems in the outlying villages and towns up to an average period of 1911, had cost $5,246,764.16.

The water supply system of the City of Chicago up to December 31, 1912, had cost $49,948,318.06. The water supply system of the outlying villages and towns within the Sanitary District, so far as the same can be obtained, has cost about $2,000,000 for five towns out of seventeen outside of Chicago, but inside the Sanitary District. No allowance is made for interest during construction in these figures. Adding the expenditures of the Sanitary District as given above, brings the total amount expended for water supply and sewage disposal up to the total sum of $150,908,189.64. If all charges could be obtained and the methods of work known, this figure would be materially increased.

The purpose of the works of the Sanitary District of Chicago is to provide for the proper and efficient sewage disposal, and to protect the water supply from pollution; and in so doing to so dilute the sewage that local nuisances will be prevented within the corporate limits of the Sanitary District; and to dilute this sewage with a minimum flow of 3⅓ cubic feet per second for every 1,000 people sewering into the channels of the District, so that nuisances will
1615 be prevented in the Des Plaines and Illinois Rivers below the end of the works of the Sanitary District.

For the disposal of the domestic sewage, 3⅓ cubic feet per second per thousand people draining into the channel is sufficient.

The effect of the flow through the Main Channel is to dilute the sewage coming from the Sanitary District to such an extent that it avoids all local nuisances in the Main Channel itself, and in the Des Plaines and Illinois Rivers. It flushes out the Chicago River, and the Des Plaines River from Joliet to the Illinois River is thoroughly flushed under summer conditions; whereas, formerly there was practically no flow in the Des Plaines River north of the junction of the Kankakee and the Des Plaines. This continued for many months in the year.

In the Illinois River, the effect has been to produce a constant flow, and it has improved the conditions of the water of the Illinois River all the way to the Mississippi River, over what it was under summer conditions.

The effect has also been to improve the navigation in the Des Plaines and the Illinois Rivers, by increasing the dry weather flow and giving greater depths. This also, as stated, has improved the sanitary conditions, by affording increased dilution for the cities and towns sewering into the river below Chicago.

The value of the water powers on the Illinois River has also been increased, by increasing the flow.

The value of the fish and mussel industry in the Illinois River has materially increased since the opening of the
1616 Main Channel. In my opinion this improvement is almost wholly due to the maintenance of a cleaner condition of the river, and the additional food furnished by the products of the self-purification of the stream for supporting fish life.

The fishing industry has gradually increased in value. The figures given in the special report of the United States census for 1908, on the Fisheries of the United States show that the fisheries in the Illinois River have grown as follows:

Year	Tons	Value
1894	3,000	$162,000
1899	7,000	382,000
1908	23,000	860,000

Besides the growth of the fishing industry, there has been a great increase in the mussel industry. The mussel shells are used for making buttons. This is shown by the following table, taken from the special report of the United States census, 1908:

Year	Tons	Value
1894	24	$ 700
1899	2,500	43,000
1908	20,000	184,000

And in that time there was also $170,000 worth of pearls taken from these mussels. From the investigations of the Sanitary District, it appears probable that the amount of fish now caught exceeds the figure given by the census of 1908.

The conditions in the Chicago River prior to the opening of the canal have been described. The Illinois River was a slow, sluggish stream in the summer time, having a very small discharge, and in times of run-off of melting snows and heavy rains, the discharge was quite voluminous. The condition of the river was that it was a polluted stream, particularly below Peoria where the sewage from Peoria and the wastes coming from the distilleries polluted the water to such an extent that it was practically a nuisance. From a navigation standpoint there was some little navigation maintained by dams, which produced slack water, and it was generally navigable from Utica to the Mississippi.

1617 Since 1909 regular examinations, both chemical and bacteriological of the waters of the Illinois River, showing the effects of the Drainage Canal upon the Des Plaines and the

Illinois Rivers have been made, and it shows that the waters are in good shape from the standpoint of the oxygen content below Marseilles. This has been carried on continuously for the last several years.

The same investigations have been made in the Main Channel, in regard to the condition of the combined sewage and fresh water, by having the water analyzed regularly. Up to the present time pretty nearly all of the manufacturing wastes from the city have been going into the sewage and channel without any preliminary treatment. There has been some slight treatment by means of removing part of the settling solids from certain industries. The result has been that there has been large accumulations of deposits in certain parts of the channel, where at times in the hot weather local nuisance is present; but the condition is now so much better than it was prior to the opening of the canal, which parallels the old Illinois and Michigan Canal, which prior to 1900 ran its capacity full of septic sewage, water and mud, so that the improvement down the Des Plaines Valley has been considerable, but at the same time there has not been sufficient water to take care of and properly oxidize both the domestic sewage and the manufacturing wastes, coming from the large industries in this city. There are large deposits of sewage mud in the Main Channel from the end of the narrow earth section that I have spoken of to Willow Springs where the rock section starts. There is practically no sludge deposits in the rock section until Lockport is reached, where the Main Channel was widened out for the purpose of making a basin at the controlling works, and in the stretch of the new channel built for the development of water power. In these stretches of the channel, there have been big deposits which in the summer time produce gas and are in a fair way to make a local nuisance. In the vicinity of the controlling works, odors are at times perceptible. This is where the deposits occur principally.

1618 The flow in the Main Channel in the last few years has been practically what is called for by the law, but prior

to that it was not up to what was called for by the State law, for the reason that the Chicago River had not been improved and the District was restrained by the Secretary of War from causing a current in the South Branch of the River to exceed a mile and a quarter an hour. For that reason, the flow in the early years of the canal was not what it should have been or what was called for by the state law; that is 20,000 cubic feet per minute for every 100,000 people draining into the channel.

The following tabulation shows the population within the limits from year to year between 1900 and 1913, and the average daily flow in cubic feet per second based on the population as provided by the state law.

Year	Population Based on U. S. Census		Average Daily Flow in Cu. Ft. per Second Population Basis	
	Within Limits S. D. C.	Actually Tributary M. C.	Total	Actual
Original Limits				
1900	1,638,656	1,294,312	5462	4314
1901	1,690,874	1,331,119	5636	4437
1902	1,740,129	1,364,961	5800	4569
1903	1,789,593	1,399,014	5965	4663
Territory Annexed				
1903	1,933,694	1,543,115	6445	5144

1912	2,415,300	2,237,330	8051	7458
1913	2,468,811	2,285,993	8229	7619
Territory Annexed				
1913	2,498,660	2,285,993	8329	7619

1619 In the early part of 1908, the water power plant was installed, and the only way of measuring the water that went through the canal was to use the water wheels as a meter. These wheels had been tested in a flume at Holyoke, by which in an approximate way we could get at their discharge under different gate openings.

Recently it has appeared that these discharges are somewhat small. This is based upon measurements made and some that have been submitted by the United States Government.

The amounts shown to have been discharged through the Main Channel of the Sanitary District in the last column, includes lake water, sewage and storm water and everything that passes through the end of the canal at Lockport.

The hygienic improvement in the Chicago water supply due to the opening and operation of the Main Channel and its appurtenances was very marked after all the sewage had been diverted from the lake. The intercepting sewers were not wholly completed until 1910, but were practically completed on the south side in 1906 and on the north side in 1908. Since that time, the reduction has been more marked in the typhoid fever death rate, so that today the water supply from the criterion of typhoid fever death rate compares very favorably with other large cities in the United States and in Europe. The typhoid fever death rate is lower than in many cities having filtered water supplies. In 1912, Chicago's typhoid fever death rate was 7.5 per hundred thousand. From 1909 to 1912, the typhoid fever death rate in Chicago was lower than that of Pittsburgh, Philadelphia,
Washington and New Orleans, all of which have filtered
1620 water supplies. The rate was also lower in Chicago than
in other cities having filters; namely, Albany, Atlanta, Birmingham, Columbus, Grand Rapids, Indianapolis, Louisville, New Haven, Oakland, Providence, Scranton and Toledo.

The following table shows the total population located in Chicago, the north shore towns and the Calumet district, which drains its sewage into the lake:

After the opening of the Main Channel, January 17, 1900.

POPULATION DISCHARGING INTO LAKE MICHIGAN INSIDE PRESENT SHORE LINES OF THE SANITARY DISTRICT.

Year	Total	Between 87th Street and South Boundary of Evanston
1900	344,344	223,625
1904	405,829	265,940
1905	426,489	281,708‡
1906	206,623	57,100
1907	214,564	60,300
1908	222,506	63,500†
1909	163,748	0
1910	168,489	0
1912	177,970	0

‡39th Street pumping station district diverted in 1905.

†Lawrence Avenue pumping station district diverted in 1908.

And this lesser number from year to year, as indicated upon this table, of population discharging into the lake and within the present shore lines is due to the fact that intercepting sewers were opened from time to time, and the sewage of the population discharged into the Main Channel where it is tributary to the Sanitary District.

The third column of the table shows the population between 87th street in Chicago on the south and Evanston on the north, that has drained into the lake since the opening of the channel.

The second column shows the total including Evanston and the Calumet District.

1621 And prior to 1900, all of the sewage substantially was drained into the lake, with the exception of what was pumped through the old Illinois and Michigan Canal.

The effect of the sewage from the towns in Lake County, Illinois, is practically nil on the water supply of Chicago. These towns include Highland Park, Lake Forest and Waukegan. There are no currents in Lake Michigan, other than

varying drifts produced by the wind. The sewage discharge in Lake County nearest the Lake View crib is over 16 miles away. The population is small, so that the protection to Chicago by dilution probably suffices for many years to come. The danger is to the water supply of the villages themselves more than to the City of Chicago proper.

The effect of the sewage from the towns in Lake County, Indiana, on the water supply of Chicago, as taken from the 68th Street or the Dunne Crib is largely influenced by the condition of the Calumet River, into which these towns discharge a part of their sewage. Flood discharges will heavily pollute the water of the lake around the crib. In drier weather, pollution may occur with sudden rains. The pollution has been traced eight to ten miles into the lake.

The district is taking steps now to reverse the Calumet River and to keep the sewage coming from the Sanitary District out of it, so that in times of flood the water in the river will not be polluted with sewage. It is also negotiating with the Indiana towns to get them to remove or purify their sewage before it enters the lake or the Calumet River, to such an extent that it will be non-putrescible.

The typhoid fever death rate shows that the quality of the Chicago water supply is excellent from a hygienic standpoint, and is far purer than most of the larger municipal supplies in the United States.

1622 The 68th Street and Dunne cribs on the south, and the Lake View crib on the north are, however, exposed to possible pollution and on the north on account of Evanston not having diverted its sewage as yet. The effect on the Chicago water of outside pollution from the north of the Cook County line is very remote. Pollution from the Calumet region in Indiana is very intermittent, but may be severe in its effect on the 68th Street and Dunne cribs.

The effect of pollution coming from passenger vessels and other vessels is being minimized by the action of the city in keeping the vessels away from the intakes, and to have the

closets locked, or tanks to store the sewage in while the vessels are passing in and out of the harbor. The shipping factor is particularly of moment in the summer months. This chiefly affects the cribs at the mouth of the Chicago River.

In the recent storms, this fall, the water supply of the city has been extremely turbid at times and in consequence the newspapers have quoted the Health Department as advising the boiling of the water. The condition of the water and the attitude of the Health Department was investigated by the Engineering Department. The records of the analysis made by the Health Department laboratory shows practically no difference in the hygienic quality of the water on account of the storms. The turbidity or aesthetic appearance of the water was, however, unsatisfactory. The Health Commissioner, Doctor Young, and his laboratory director, Doctor Tonney, both admitted advising the boiling of the water in an informal way to the newspaper men, but stated that this was a precautionary measure only, inasmuch as it is impossible to learn the quality of the water by immediate tests. The bacteriological tests employed do not give results until after 48 hours have elapsed. Their opinion was the same as ours, that only the appearance of the water had been injured by recent storms, and that the hygienic quality of the water was unimpaired, rendering boiling unnecessary.

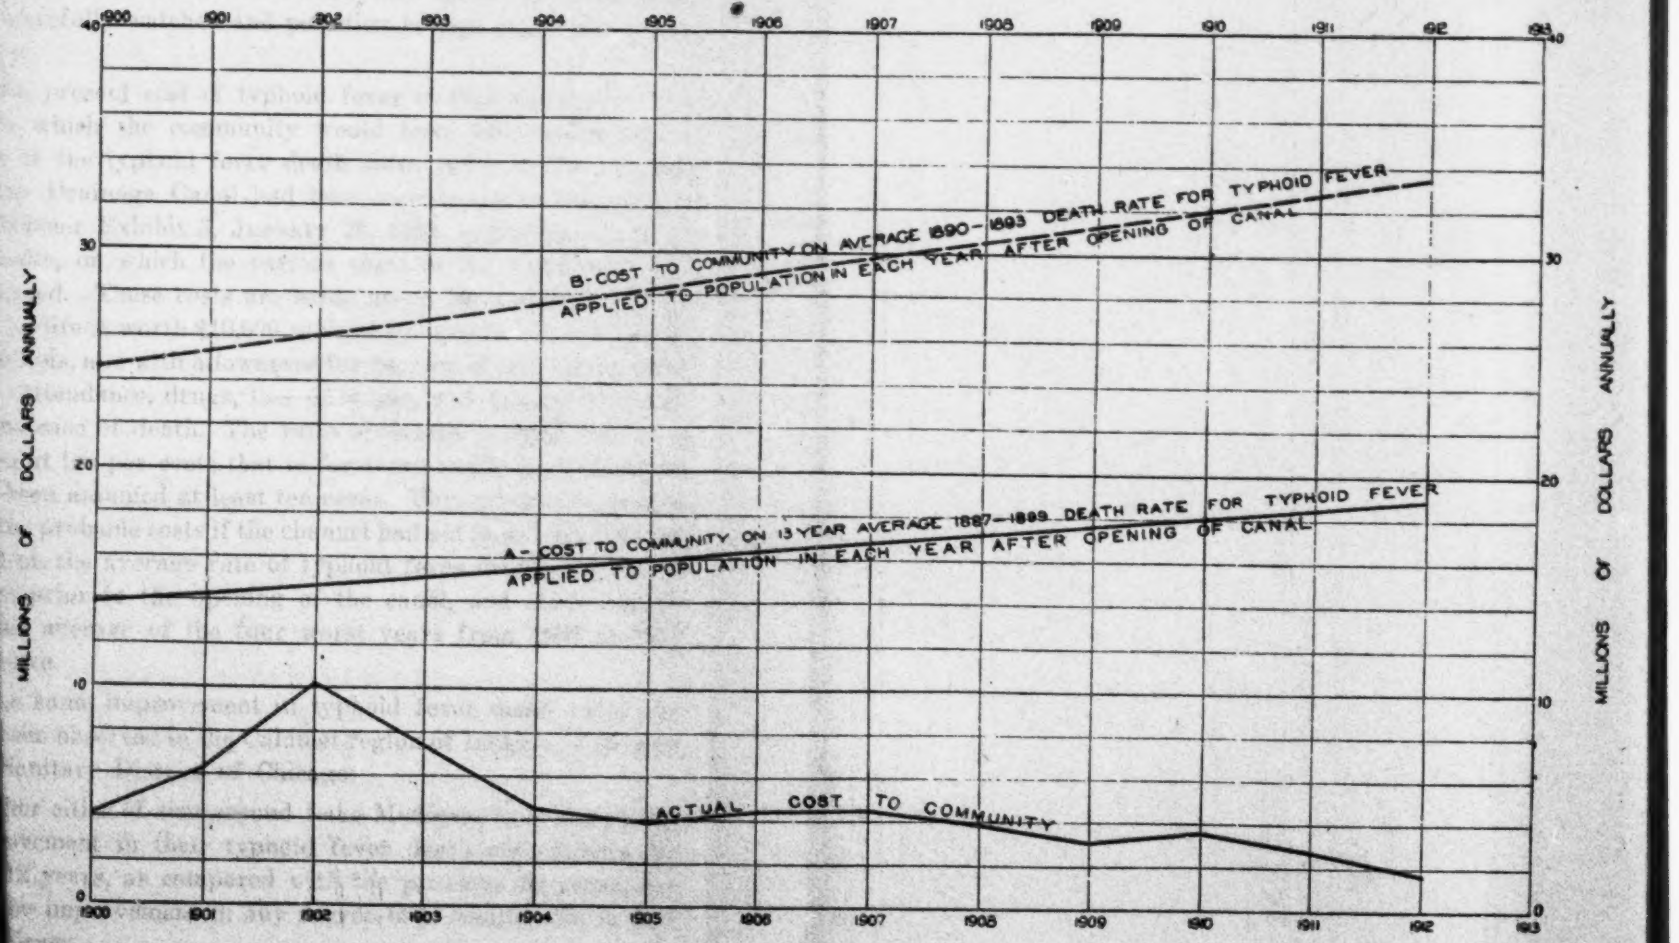
1623 For 13 years prior to the opening of the Drainage Canal, the average typhoid fever death rate was 52.6 per one hundred thousand. For the 13 years after the opening of the canal, the death rate was 19.9 per one hundred thousand. This reduction is about 68 per cent, and would have been more marked had the sewage been intercepted completely earlier in the last 13 years.

The average death rate for the diarrhoeal diseases for the period before the opening of the Drainage Canal was 418.2 per one hundred thousand. This was reduced to 187.2, a reduction of 55 per cent.

Wisner Exhibit 3, January 20, 1914.

THE SANITARY DISTRICT OF CHICAGO

CHART SHOWING SAVING TO COMMUNITY BY REDUCTION OF TYPHOID FEVER SINCE OPENING OF DRAINAGE CANAL JANUARY 2. 1900.



The typhoid fever death rate in Chicago has been reduced markedly, even compared with the reductions affected in cities where filtration plants have been installed. The rates for 1911 and 1912 were lower than the rates in the cities of Philadelphia, Washington, Pittsburgh, and New Orleans, where filtered water is supplied. They are as low as in Boston and lower than San Francisco where the water sheds are carefully watched and pollution is kept out of the reservoirs.

The present cost of typhoid fever to this community, the costs which the community would have been called on to bear if the typhoid fever death rates prior to the opening of the Drainage Canal had been maintained is best shown by Wisner Exhibit 3, January 20, 1914, appearing on page opposite, on which the various costs to the community are indicated. These costs are made up on the assumption that a life is worth $10,000 as fixed by certain statutes in Illi-
1624 nois, and with allowances for the cost of nursing, medical attendance, drugs, loss of wages, and funeral expenses in the case of death. The ratio of deaths to cases has been taken at ten per cent; that is for every death reported there has been assumed at least ten cases. Two curves are plotted for the probable costs if the channel had not been built, one figured on the average rate of typhoid fever deaths for the 13 years prior to the opening of the canal, and other figured on the average of the four worst years from 1890 to 1893 inclusive.

The same improvement in typhoid fever death rates has not been observed in the Calumet region of Indiana, adjoining the Sanitary District of Chicago.

Other cities of size around Lake Michigan have not shown improvement in their typhoid fever death rate during the last 12 years, as compared with the previous 20 years, nor has the improvement in any degree been comparable to that in Chicago.

In Milwaukee, for instance, the typhoid situation has been practically unchanged for over 30 years, the rate at times

being practically as high as 30 years ago. The improvement in Chicago has been very favorable. In Michigan City, a city of 19,000 people in 1910, the typhoid rate has been high, with violent fluctuations, extending over a range of from nothing to 112 deaths per one hundred thousand between 1882 and 1907.

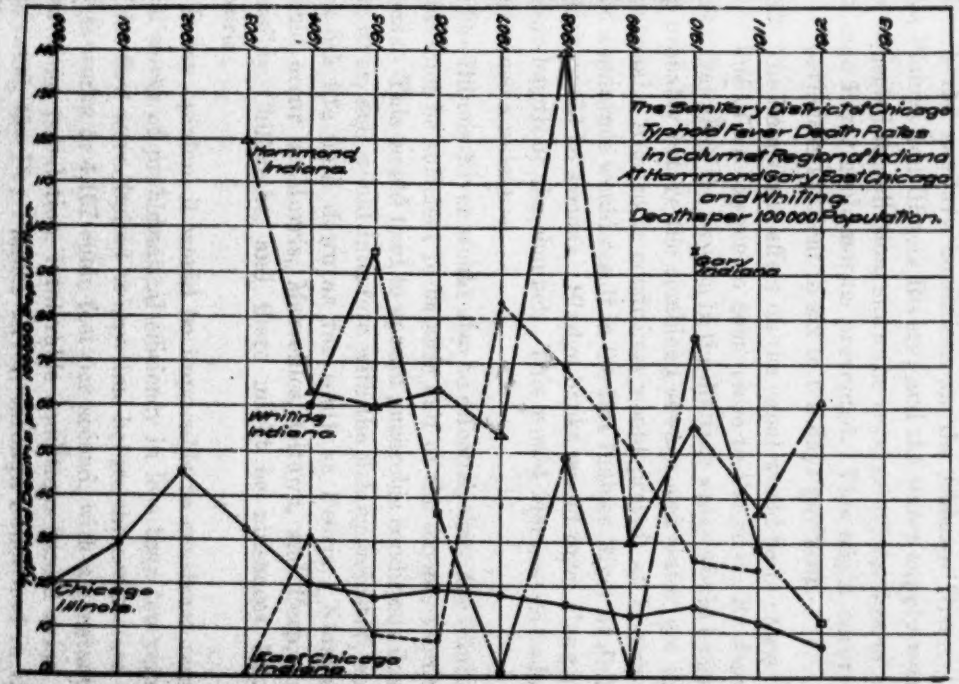
The same improvement in typhoid fever death rates in the towns in Indiana, adjoining Illinois, has not been ob-
1625 served. The current typhoid fever death rates are shown on Wisner Exhibit 4, January 20, 1914, appearing on page opposite.

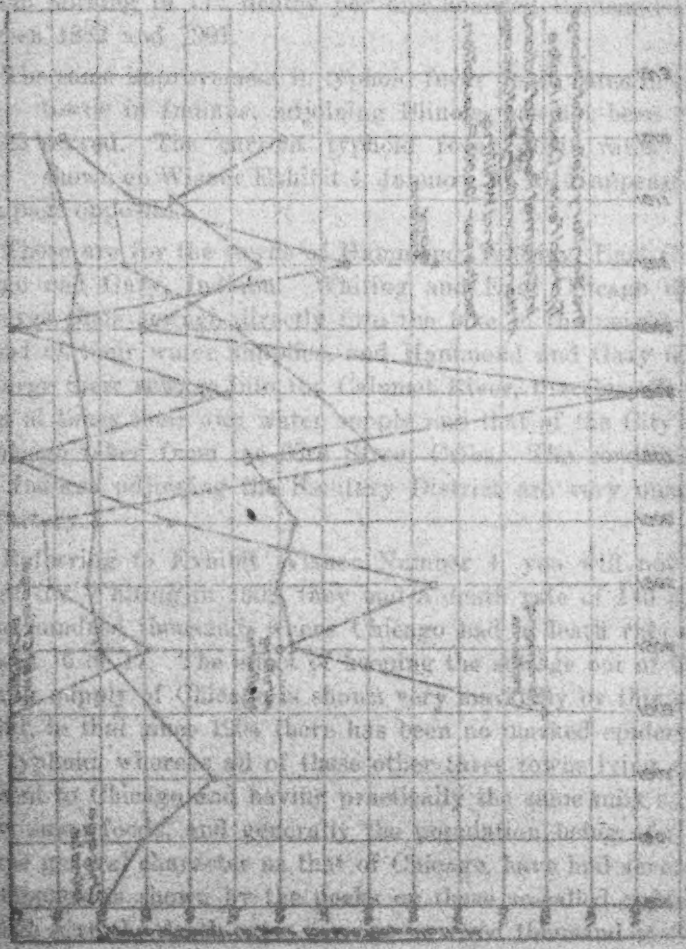
These are for the towns of Hammond, Whiting, East Chicago and Gary, Indiana. Whiting and East Chicago discharge their sewage directly into the lake in the neighborhood of their water supplies, and Hammond and Gary discharge their sewage into the Calumet River, thereby affecting at times their own water supply and that of the City of Chicago taken from the 68th Street Cribs. The conditions in Indiana adjoining the Sanitary District are very unsatisfactory.

Referring to Exhibit Wisner Number 4, you will notice that for Whiting in 1908, they had a death rate of 140 per one hundred thousand, where Chicago had a death rate of about 16 or 17. The effect of keeping the sewage out of the water supply of Chicago is shown very markedly by this exhibit, in that since 1904 there has been no marked epidemic of typhoid, whereas all of these other three towns lying adjacent to Chicago and having practically the same milk supply, same foods, and generally the population being of the same general character as that of Chicago, have had several epidemics as shown by the peaks on these so-called curves, which give the death rates per one hundred thousand of the people living in these towns.

Since 1902, Chicago has had nothing that represents an epidemic, and the line from 1904, the solid line on this exhibit, which represents the death rate from typhoid fever in

Wisner Exhibit 4.





Chicago, has been gradually going down, showing a decrease in the typhoid fever death rate.

The effect of a diversion of only 4,167 cubic feet per second would injure the quality of the water supply and seriously disturb the sanitary conditions in the Chicago River, the Des Plaines and Illinois Rivers; and the water supply would be subjected to pollution, since the reversal of the flow of the Chicago River could not be prevented. This might occur on periods equivalent to six to ten days per year.

1626 The immediate effect on the canal would be to cause the line of no oxygen to come close to the city. By that I mean that all of the oxygen in the diluting water would be used up probably before the combined sewage and water got into the canal. Anaerobic conditions would prevail at Lockport, and a nuisance would result in the Des Plaines River at Joliet which would be serious. Sludge banks would form along the whole length of the channel. This would increase the odors and cause a nuisance.

The Illinois River would also be affected, since the dilution would not be sufficient to balance half of the oxygen requirements. This would tend to spread anaerobic conditions down the river, and would interfere with the fishing industry, ending fish life until down as far south as Peoria. Nuisance would occur at Morris, Marseilles, Ottawa, and Peru, and possibly Chillicothe, and there might be nuisances below Peoria.

In my opinion, it would be impossible to construct remedial works of problematical efficiency in less than ten years. If the flow were limited at any time before the completion of these works to 4,167 cubic feet per second, with a constantly increasing population, intolerable conditions would arise in the canal, the Des Plaines River, through Joliet and in the Illinois. Conditions in large portions of the Chicago River proper would be a living nuisance. Sludge would accumulate in the Chicago River.

In times of high water when the river was reversed as just mentioned, this accumulation of sludge would probably be scoured into the lake, polluting the water supply with the sewage polluted water of the river itself.

Assuming that the flow were reduced at once to 4,167 cubic feet per second, there is no thoroughly satisfactory emergency treatment. If the flow were continued in accordance with the minimum ratio of 3 1/3 cubic feet per second, a double expense would be thrust upon the Sanitary District, as it would have to develop the canal to a capacity of 12,000 cubic feet per second before the other works could be put into service.
1627 The only suggestion would be the use of an excessive amount of chloride of lime. This would be unsatisfactory, as the sludge would still go into the river and create nuisance, and in addition would be very costly. Time would be required to install emergency works on such a large scale.

The daily floating population by 1920 in Chicago will be 300,000 people. There is today a transient population of 68,000,000 in the course of a year, including through and local travellers from outside the boundaries of the district, who may be assumed to come in contact with conditions in the City of Chicago.

The records obtainable from the different railroads coming into Chicago were obtained and these figures compiled from figures given to us; and also from steamship companies.

The people were counted coming into the stations for a certain length of time to get an estimate of the number of people where the railroad companies had no sufficient data at hand.

The probable population of the Sanitary District in the years 1920, 1930 and 1940 is based on the United States census reports, and upon the probable growth of the city in the future as based upon what it and other large communities have done in the past.

The amounts of water required for the population based upon the minimum legal flow for dilution and compilation with reference to future population are as follows:

Year	Population	Flow required in Cu. Ft. per. second
1910 Actual	2,308,276	7694
1920	3,110,036	10367
1930	3,866,023	12887
1940	4,466,000	14900

1628 The available methods for the sewage disposal of large cities comprise dilution, screening of the sewage, sedimentation, which is removal of the settling suspended matter by settling in various types of tanks, chemical precipitation, broad irrigation or land irrigation, intermittent filtration, contact beds and sprinkling filters. These methods may be used in combination, according to local circumstances or conditions. Sterilization by the use of chloride of lime, or liquid chlorine, may also be used on raw sewage and effluents of treatment works.

Screening is useful principally to remove coarse floating material. Sedimentation may remove most of the settling suspended matter, and improve the stability of the liquid from 15 to 25 per cent. Chemical precipitation will remove somewhat more of the settling suspended matter and some of the colloidal matter. In order to make a stable effluent after the suspended matter has been removed, treatment to oxidize the organic matter is required. This is frequently carried out in bacteria beds or biologic filters. Such processes include broad irrigation, intermittent filtration, contact beds and sprinkling filters. These methods, however, are not all equally practicable.

The methods of broad or land irrigation and intermittent filtration require very large areas of land. In the United States, broad irrigation is practically abandoned, save in the

arid regions, where it is of value principally for the water rather than for any other purpose. Intermittent filtration is not now installed for large cities, but is considered practicable for small towns under 10,000 population, where sand is cheap and land valuable. Sprinkling filters and contact beds are more practical for large cities as a larger population can be taken care of on smaller areas. Of these two, the sprinkling filter is most economical and efficient, as a rule.

The dilution method, by the use of the main channel and a supply of water from Lake Michigan, is the most economical and efficient, the surest and the most effective, in that it diverts all the sewage from the water supply, and 1629 works automatically; is not dependent upon any individual or individuals for its efficiency; and permits of self-purification of the sewage in the ordinary and natural way.

For handling the sewage of the Sanitary District in case the flow required by the legal ratio is restricted, settling would be the first step to bring about the removal of settling suspended matter. This could be followed by the use of sprinkling filters to produce a stable effluent, as required. Secondary settling basins would probably have to be used to remove the humus formed in the sprinkling filters. Sterilization by chloride of lime or liquid chlorine might be utilized on storm flows and sewage effluents as required by circumstances.

No allowance has been made for the industrial load, as it is recognized that whatever happens the industrial sewage would have to be cared for in any case. This means that the cost of handling the industrial sewage would be additional to all of the comparative estimates submitted. This has been recognized by the Board of Trustees, and special studies are now being conducted by the engineering department of the District to determine the methods of treatment for the industrial wastes, principally for those of Packingtown and the Stock Yards, and for the tanneries.

The dry weather sewage flows vary from 170 to 600 gallons per capita. An average flow of 300 gallons, about,

per capita, has been estimated from a study of the flows actually found on various typical areas by gagings made by the Sanitary District of Chicago. The storm flows vary considerably. Maximum storm flows have been found from 50 to 70 cubic feet per second per square mile on areas of some size, with a maximum of 128 cubic feet per second per square mile on small well built areas. Intercepting sewers planned for a flow equivalent to 900 gallons per capita daily are required to care for the first rush of storm flows, and the minor storms.

1630 Assuming that 4,167 cubic feet per second of water are available from Lake Michigan for dilution, the cost to the Sanitary District for handling population equivalent to diverted flows amounting to 10,000—12,000 and 14,000 cubic feet per second by means of these additional works are given in the following table:

	3,519,440.00
8. Depreciation,	1,182,157.00
Total,	$4,701,597.00
9. Pro-rated for increase of population from 3,000,000 to 3,600,000 equivalent to a diversion of 12,000 c. f. p. s.	5,650,000.00
10. Pro-rated for increase of population from 3,600,000 to 4,200,000 equivalent to a diversion of 14,000 c. f. p. s.	6,590,000.00

This scheme contemplates the construction of intercepting sewers based on a dry weather flow of 300 gallons per capita per day, carrying flows up to 900 gallons per capita per day to Central points for treatment. Above this amount, the storm flows would be discharged into the Chicago River or Calumet River, with sterilization; special tanks being provided to give a contact of 10 minutes on flows based on the maximum peak discharges. Coarse screens and grit chambers are contemplated, with facilities for cleaning. Set-
1633 tling basins are also to be built of the double deck type for dry weather flow, with capacity up to 900 gallons per capita. Sprinkling filters are estimated for the excess population which cannot be cared for by the extended use of settling tanks. The estimates include the sterilization of all the sprinkling filter and settling tanks effluents before being discharged into the Chicago River or the Canal. The double deck tanks would be designed on a basis of two hours retention of 300 gallons per capita daily in the settling chamber, and six months retention of sludge. The sprinkling filters would be designed on a basis of 12,500 people to the acre, the filters being assumed to be 6 feet 4 inches in depth of filtering stone. Secondary settling tanks are to be used for the filters, nominally of half the size of the primary settling tanks.

The estimates given are based on the current cost of sewer construction in the City of Chicago, due allowance being made for the probable character of the work, the cost of labor and material, and the character of the excavation to be made. The cost of the pumping station is based on $500 per water horsepower, the amount being adjusted slightly to scale down for the larger installations. Such costs are based on the known cost of the existing pumping stations in the city of Chicago. The cost of the settling tanks and appurtenances is based on careful estimates made from detailed drawings for a unit plant designed to care for 40,000 people. The appurtenances include a Venturi Meter, grit chamber, sludge drying beds, office building, laboratory, walkways, roadway,

electric lighting, and the general appurtenances required. The cost of land has been estimated from actual cost of land purchased by the District for its right-of-way for channels, and current sales of real estate in the City of Chicago. In each case, an allowance has been made for the probable increase in future costs.

1634 The annual cost includes an allowance for labor, repairs and supplies for the operation of the grit chamber, settling basins, sprinkling filters, secondary settling basins, the cost of labor and supplies for the disinfecting plants; the cost of labor, fuel, supplies, and repairs for the pumping stations; depreciation on all structures; interest during construction at 4¼ per cent for the entire construction cost for one-half the period estimated for construction. The allowance however made on land is the interest on the cost for the entire period. In the making of the estimates for sterilization, chloride of lime has been used as a sterilizing agent for the effluent of settling basins and sprinkling filters, whereas liquid chlorine has been estimated for handling the storm flows, in order to have available a large potential supply of chlorine for immediate use on sudden storms.

The capitalized cost of the foregoing schemes, including in capitalization the construction cost, as well as the capitalized cost for maintenance, operation and depreciation are given in the following table:

CAPITALIZED COSTS OF SEWAGE TREATMENT BASED ON DIVERSION OF 4167 C. F. P. S.

Treatment Equivalent to Diversion of Cu. Ft. per Sec.	Construction Cost	Capitalized Operating and Depreciation Cost	Gross Capitalized Cost
10,000	$72,884,471	$110,625,800	$183,510,271
12,000	87,200,000	132,941,100	220,141,100
14,000	101,900,000	155,058,800	256,958,800

These costs are supplemental to the present expenditures made by the Sanitary District which have been given as construction and operating costs.

The combined total costs, covering construction and capitalized annual maintenance and depreciation, combining the existing investment of the District with the investment required to produce with a reduced flow of 4,167 cubic feet per second the equivalent of conditions of flow of 10,000—12,000 and 14,000 cubic feet per second are given in the following table:

1635 CAPITALIZED COST OF SEWAGE DISPOSAL COMBINING COST OF NEW TREATMENT WITH EXISTING INVESTMENT BASED ON DIVERSION OF 4167 C. F. P. S.

Treatment Equivalent to Diversion of Cu. Ft. per Sec.	Capitalized Cost New Works	Gross Capitalized Cost of Existing Works to Dec. 31, 1913	Total Gross Capitalized Cost
10,000	$183,510,271	$76,067,600	$259,577,871
12,000	220,141,100	76,067,600	296,208,700
14,000	256,958,800	76,067,600	333,026,400

Studies have been made of receipts from taxes in the past by the Sanitary District, and a study has been made of the probable increase in the taxable value of property within the Sanitary District, so as to estimate the amount of bonds that can probably be issued by the Sanitary District, and from these have estimated what the highest possible income could be up to 1925, by issuing all of the bonds it is possible to issue, and getting all of the money from general taxation that it is possible to get, and the amount available from 1914 to 1925 inclusive would be $54,729,000 approximately.

There has been compiled from the books of the District and from estimates the probable investments required in the next ten years to cover extraordinary repairs and to settle obligations on contracts, assuming that all existing contracts for construction are terminated on December 31, 1913. This includes the amounts necessary to complete the North Shore and Evanston intercepting sewers, to improve the Des Plaines River in the territory recently annexed, to adjust the conditions in the North Branch of the Chicago River, to build cer-

tain docks in the Main Channel, repair walls at Lockport and Joliet, and to carry a share of the expense of handling the industrial wastes. This amounts to $11,577,000. This
1636 would be deducted from the available resources given, thus reducing the net amount available for new works to $43,152,000 approximately.

It would not be possible to finance this plan with the net revenue available within ten years. Not only would the construction costs have to be met, but also certain operating costs, as parts of the works were finished and put into service.

1641 A diversion up to the full capacity of the rock section, viz.: 14,000 cubic feet per second is the most economical way of developing the resources of the Sanitary District for sewage disposal and is shown by the following table which shows the amounts which would have to be expended by the Sanitary District under the different alternative methods, first of dilution, and second of treatment, to produce approximately the same result in the treatment of the sewage. This scheme for treating the sewage with a diversion of 4,167 cubic
1642 feet per second, and the use of the supplemental works, is not as effective in protecting the water supply as the diversion of from ten to 14,000 cubic feet per second.

COMPARISON OF CAPITALIZED COST TO SANITARY DISTRICT FOR EQUIVALENT DIVERSIONS OF 10,000, 12,000 AND 14,000 CU. FT. PER SEC.

Existing Works plus Treatment on Basis of Diversion 4167 Cu. Ft. per Sec.	vs.	Extension Dilution from 10,000 to 14,000 Cu. Ft. per Sec.

Equivalent Diversion of Cu. Ft. per Sec.	Existing Works with 4167 C. F. P. S. Plus Treatment	Extension of Dilution, Gross	Extension of Dilution, Net*
10,000	$259,577,871	$76,067,600	$62,825,600
12,000	296,208,700	95,517,070	77,720,070
14,000	333,026,400	102,519,910	80,213,900

* This allows credit for Electric Dept. earnings.

As to the efficiency of the various methods of sewage treatment, the factors taken into consideration, in reaching the above conclusions are:

One factor is that of the known methods in 1887-1890, and even up to 1900. The present method of dilution is the only one available for handling the sewage of cities over 100,000 population, which has survived the test of time. We have definite knowledge of the workings of the Main Channel from 1900 to 1913, with the severe tests which actual continued use imposes. Of the alternate schemes, no one can show a continued use so long, nor an application on so large a scale.

Another factor has been the attitude of sanitary engineers and sanitarians in general. There is no sanitary engineer or expert qualified to speak authoritatively who does not say that the diversion method installed at Chicago is the best method for that locality. This opinion is found held not only by American but also by foreign experts.

For many years many engineers and others, particularly laymen, residing in and out of Chicago, had criticised the dilution method of sewage disposal, as exemplified in Chicago. In order to satisfy the Board of Trustees on this point, a testing station finally was authorized in 1909.

1643 This testing station has been running continuously ever since. The results obtained and the studies made on the canal and the Illinois River have only served to confirm my opinion that the method of diversion and dilution is the best, the safest, and the most economical for the local situation.

At this sewage experimental station at 39th street, and the second one at the Stock Yards, where the wastes of that industry are being tested at these places, we have tested out every known device that would be applicable to the treatment of sewage in this locality.

As an engineer, I have had serious doubts concerning the practicability of works for treating sewage on such a large scale. This does not come from fear or ignorance of the correct principles to follow, but is based on conservatism,

Wisner Exhibit 6, January 20, 1914.

ELEVATION OF WATER SURFACE ABOVE SEA LEVEL

induced by lack of precedent anywhere for the partial or complete treatment of sewage on such a large scale. There are many novel problems involved. One of the greatest difficulties in the way is the securing of suitable sites. Judging by the opposition developed in Chicago recently in the various wards to the location therein of garbage treatment plants, I would anticipate serious delay in obtaining the sites desired. Public sentiment, even though wrong, is slow to recognize the necessity of certain locations. Another condition that might work adversely to artificial sewage disposal is the climatic conditions of Chicago, where severe winter weather is encountered. Most of the plants that I have seen in operation do not have the severe winters that Chicago experiences.
1644 So far as the towns in the Illinois River Valley, exclusive of Joliet on the Des Plaines, are concerned, ample dilution has been afforded. It is possible that if only the natural flow of the Illinois River were available that the low flow would be insufficient today for the dilution of their sewage alone, provided local nuisances were avoided. Coarse screening and possibly sedimentation might have to be installed. The cost of this I have not studied, other than to note the probable need of additional expenditures over and above those now made for sewer systems. On the Des Plaines River, however, Joliet would have had an absolutely inadequate dilution, which would have necessitated complete treatment of the sewage at a probable cost, pro rated from our estimates for Chicago of about $1,000,000. This has been saved by the flow from the Sanitary District to the City of Joliet.

A diagram (Wisner Exhibit 6 shown on opposite page) has been prepared which has been brought up to date, month by month, showing the lake levels at Chicago, taken from the publication of the United States Engineer's Office, and the Lake Survey, and corrected to date in accordance with the monthly bulletin issued from the office of the Lake Survey at Detroit. This shows that the average lake level for the eleven years following the opening of the canal was 580.63 ele-
1645 vation referred to mean tide at New York, or 0.22 of a

foot higher than the average lake level for the eleven years prior to the opening of the canal, which was 580.41 elevation referred to mean tide at New York.

High lake levels will increase the cost somewhat of new sewers by reason of the ground water, but the principal influence is in retarding the efficient operation of the sewers by backing up the water in the sewers to a greater distance from the mouth, and probably permitting thereby the stranding of solid materials which is very undesirable. The engineer in constructing the sewerage system plans to put the sewers at a certain depth below the surface to permit discharges of liquids from cellars and to get grades which will produce safe velocities at low flows. With the flat topography of the City of Chicago and the back water produced by the lake, it is extremely important to produce the best working conditions on the intercepting sewer systems, which necessitates pumping and great increased cost.

Frederick P. Stearns, a witness for the defendant, his qualifications being heretofore given, (This Narrative p. 134) testified as follows, October 13, 1913, (Vol. II, pp. 1074, 1075):

The canal was built for 10,000 cubic feet a second, and I believe has a still larger capacity. And it was built to reverse the current in the Chicago River, so that that river which receives sewage should not be turned into the lake. And time is an important element in producing any change in sanitary conditions; and I do not believe that if the quantity were diminished to 4,167 cubic feet per second, that the city could catch up with those conditions, even. If the quantity had been fixed originally, they might possibly have purified the sewage to the extent so that they could get results from that quantity which were fairly satisfactory, except for the reversal of the river currents. There is a necessity for reversing, also, in ordinary times, the current of the Calumet River, in my judgment, so that the ordinary flow of the Calumet River should not be into the lake.

George W. Fuller, a witness for the defendant (Rec. Vol. III, p. 1409-1515) November 17, 1913:

Resides Summit, New Jersey; place of business New York City; hydraulic and sanitary engineer, making a specialty of matters of water supply, water purification, sewerage and sewage disposal; graduate of Mass. Inst. of Tech. in 1888; studied at Berlin Hygenic Institute, took special courses relating to the practical art of water filtration, 1888; 1890 in the office of Piefke, engineer of the Berlin Filters; 4½ years on Technical Staff of Mass. State Board of Health; at Law-
1410 rence from spring of 1891 until the autumn of 1895. The station at Lawrence was conducted by the Mass. State Board of Health with a view to ascertaining the best means of purifying water and sewage under local conditions in Mass.; succeeded Mr. Allen Hazen in March, 1893, as the man in charge; was 4 years at Louisville, Ky., and Cincinnati, Ohio, in ascertaining the best means in point of efficiency and economy of purifying the muddy polluted Ohio River water; since summer of 1899 has been in practice in New York City; 1901-1911 in partnership with Rudolph Hering in hydraulic and sanitary work; was connected with upwards of 100 different sewage disposal projects and an equal number of water supply and water purification projects; for 9 years was a member of the Board of Advisory Engineers at New Orleans, having to deal with the expenditure of some $20,000,000 on drainage, sewerage and water supply projects; connected with the Passaic Valley Trunk Sewer project in New Jersey, with regard to getting out the preliminary estimates of cost of that project to serve about 1,600,000 people; has been connected wtih the litigation before the U. S. Supreme Court in connection with the pollu-
tion of N. Y. Harbor waters by that sewer; connected
1411 with the design of the sewage treatment works at Columbus, Ohio, serving as consulting engineer during their construction similarly at Reading; was connected with sewage disposal designs in thirty or forty different instances, the more recent ones being Atlanta, Georgia, Schnectady, New York, Al-

toona, Pennsylvania, Norristown, Pennsylvania, and a group of cities in New Jersey in what is known as the Plainfield District. On water supplies, was a member of the committee appointed in 1901 by the U. S. Senate to consider water supply matters in point of purification of the City of Washington; consulting engineer for New York City, both as to Catskill project and the existing Croton water supply; also connected with water supply projects, including St. Louis, New Orleans, Louisville, Cincinnati, Columbus, Ohio, Minneapolis, Grand Rapids, Montreal, etc. Has followed the development of the art of sanitary engineering in Europe; made a number of visits to Europe for that purpose. During
1412 the World's Fair in 1893 at Chicago had spent a number of weeks and had charge for a time of the exhibit of the Mass. State Board of Health; took occasion then to look into the water supply and sewage disposal matters at Chicago; 1901 was called in as expert by the St. Louis Water Department with reference to the treatment of the then existing water supply of St. Louis; in 1903 was one of the experts in the Drainage Canal litigation, *Missouri* v. *State of Illinois*, with Mr. Rudolph Hering; made an investigation and report to the International Waterways Commission with reference to Chicago Sanitary District; 1909 had to do with testing a filter plant in the stock-yards district.

The witness testified further as follows:

1413 Was familiar with the conditions at Chicago in 1889 and prior thereto, and prior to the opening of the Drainage Canal in 1900.

Briefly stated, in 1889, the sewage of the residents of this community adjoining the lake front, and for some distance back from the lake front, discharged into the lake. The water supply was then taken from a number of cribs connected by a tunnel, and located in Lake Michigan at comparatively short distances from the shore. I speak of dis-

tances to emphasize the point that the tunnels were then not so far out into the lake as at present. The sewage from portions of this district removed from the lake shore discharged into the Chicago River and its various tributaries.

There was at Bridgeport an old pumping station of a capacity of something like 1,000 seconds feet; and the purpose of that station was to lift the sewage polluted waters of the Chicago River, and send them through the old Illinois and Michigan Canal down into the Valley of the Des Plaines River in the vicinity of Lockport. The water supply conditions in point of pollution with sewage were notoriously bad, as shown by the records of death rate from typhoid fever and other water borne diseases. The pollution of the lake water at the intake-cribs, where the water was drawn for the public supply of this district was brought about, with substantial regularity, by the flow of sewers discharging directly into the lake. The conditions at certain times were much worse than this, and then the accumulations of sludge in the Chicago River and its tributaries, at times of very heavy rainfall, were flushed out into the lake and unquestionably had a very deleterious influence upon the hygenic quality of the water supply at the intake cribs, and as sent to the water consumers of this general district.

That outlines the condition in 1889, so far as the main features are concerned.

1419 In 1889 as regards the protection of water supply, the larger cities having the foremost sanitary advisors, recognized the importance of keeping sewage out of water supplies. That was about the date when the early beginnings were made of separating sewage from water supply. In some instances, efforts were being made to locate new intakes for cities situated on rivers, so that the water would be taken from above the discharge of sewage. It was recognized that where this was not feasible, intercepting sewers should be built for river cities, so that the sewage would enter the stream below and not above the river intakes.

There was at that time nothing known at all about the sterilization of public water supplies. In this country, there were practically no water filters in towns of any considerable size. For 20 years the art of water purification had been dormant.

In the late sixties, Mr. Kirkwood, one of the leading American engineers, studied water filters as practiced in Europe, and had made an extensive report in the interests of the City of St. Louis. It was not thought wise, however, to build filters from information then available.

1420 There were one or two filters built in the Hudson River Valley at Poughkeepsie and Hudson, New York, but with that exception, there were no sand filters in existence in this country.

Mechanical filters, as now known, were practically unheard of and were then merely crude straining arrangements in use in mills and other industrial establishments, with a few scattered plants that were just beginning to be installed for some municipal supplies. In those days, the germ theory of disease, as I have already explained, was not generally recognized; and while there were sand filters in Europe, they were essentially clarifying devices, and the benefit to the hygienic quality of the water appeared to be a mere incident. In other words, there was practically nothing known in the art of filter filtration which had associated with it well defined laws which would allow hygienic accomplishments to be reliably secured. American engineers were afraid of water filters in those days, owing to the wide differences in climatic conditions as compared with European facts and conditions; and furthermore they had nothing to serve as a practical guide as to how they should build the filters to secure effective accomplishments at all times, under the wide range of local factors, climatic, and relating to the water itself.

I can best illustrate the negligible working art of water supply in 1889 by saying that I was at that time connected with the Massachusetts State Board of Health, and even a little later on their attitude was one of not knowing how to advise

the City of Lawrence to filter a grossly polluted water supply, at a time when severe epidemics of typhoid fever were raging.

In fact it was not until 1892 that experiments even were made at the Lawrence Experiment Station to work out what might be called the laws of filtration, which are the basis of water filtration of subsequent years.

1421 The hygienic improvement in the Chicago water supply due to the Drainage Canal is decidedly greater and better than could have been obtained by improving the water supply in other ways as known to the art of 1889. In other words, the diversion of the sewage from the lake and from the Chicago water supply was far better than to have attempted to try any other means for getting a pure water supply, as those means were known in those days.

At that time there were three methods that were studied for large cities. There was the dilution method, which was by far the most prevalent method, and there were available two other methods which had been tried somewhat in certain of the European countries where large centers of population had sprung up upon very small water sheds. Those methods other than the dilution method were known as chemical precipitation and land treatment. In explaining these last two terms, I will say that land treatment grew out of an effort to apply sewage to farm lands, in order to take advantage of the manurial properties of sewage.

It had been tried, for instance, here in the Chicago district, at Pullman, and it was found that the land was not suitable for such purposes.

In regard to chemical precipitation, that was a method of applying certain chemicals like lime, alum and iron sulphates to sewage, allowing the treated sewage to pass through tanks holding several hours' flow;and in the tanks there would be deposited the course sewage filth. Those chemical precipitation works in England that were then in existence, had their origin also in efforts made commercially to secure the manurial properties of the solid sewage substances. They were not

a success commercially, as to the securing of fertilizing properties at a cost which would be at all warranted on a large scale. They were essentially clarifying arrangements, and were then in considerable vogue, owing to the efforts
1422 made in London to clear up the lower Thames, which had very foul decomposing banks of sewage sludge in its lower reaches.

I might say that there were some little contrivances, called clarifying or straining arrangements, which were practiced at places like Atlantic City and Long Branch, in order to keep the sewage solids away from the more prominent sea shore bathing beaches, but they were very short lived and are not worthy of any serious consideration in a project such as then existed at Chicago.

Chemical precipitaton method did not produce a treated product so that you could safely discharge that treated sewage, clarified sewage into a stream or into a lake and have a safe water supply. It was a clarifying process and not one for removing completely disease germs. In fact it was applied, not with a view of protecting water supplies but solely to eliminate sewage sludge, prevent these foul decomposing masses of sludge, and that alone was its true function. It was not a means of protecting a source of water supply.

Sewage farming method in this country, has never been used with any success commercially. In fact, the method, even in our arid western states has had a very limited and merely nominal scope of usefulness. The reason of that is that it costs more to get the sewage to farm lands surrounding a large city than is the worth of that sewage for fertilizing purposes, or for irrigating purposes, or for the two combined. That is very well demonstarted by the experiences of Los Angeles, for instance.

Twenty years ago, the sewage from the outfall sewer at Los Angeles was used in sewage farming, but the resentment of the public to having garden truck come in from districts where it was known that sewage was used on the farm lands,

the odors which arose from the pooling of the sewage on the farms, and the interference with land development projects even miles away from sewage farms, all led that city, with a rainfall of only ten or twelve inches per year, to abandon sewage farming and build a new outfall sewer to the Pacific Ocean.

What I have said with regard to Los Angeles applies, to every other sizable city in our arid districts. It is not difficult to find references in official publications to
1423 some nominal use of sewage for sewage farming in the western states, but a careful examination such as I have given to these subjects, shows that the sewage has been used simply for its irrigating purposes, at times when it would be of benefit to the farmer, and that on other occasions it has been diverted to the nearest water courses.

In our eastern states, the matter stands in quite a different attitude, because the rainfall is generally sufficient for farming purposes, and when there is ample rainfall the farmers are in all cases, disposed to divert the sewage to some water course, or to allow it to build up on certain portions of the farm lands where it putrifies and produces nuisances.

Briefly stated, the attitude and experience in this country with regard to sewage farming, I would say that the method has never become well established, even for small cities, and it is entitled to no established footing or standing for the problems of large cities. That is true in the west, and still more so in our eastern states.

In 1889, I take it all sewage was disposed of by dilution. There are some instances where sizable towns have grown up on very small streams, where treatments works of some kind or another have come up for consideration, but today it is safe to say that somewhere from 93 to 96 per cent. of the sewage of all towns and cities is disposed of by dilution. Where it is not so disposed of, the dilution method is not a candidate for consideration, because of the small volume of water available for diluting purposes.

There are a few other exceptions along harbor towns, for instance, where shell fish pollution has been a factor.

Broadly speaking then the dilution method which was practically in universal use in 1889, has continued to be the prevailing one. In fact it is always applied to-day where the conditions allow of its being applied under reasonable conditions.

The sewage farming method that I have spoken of already is on the wane decidedly, in Europe. The largest sewage farm in England, at Birmingham, has been practically abandoned. In Paris, it is being gradually given up, and, beginning a couple of years ago, they are installing sprinkling filters to take the place of sewage farms now located in part in the growing suburbs of the district.

1424 In Berlin, the sewage farms are still used, where the conditions are very favorable as regards light, sandy, porous soil, on lands that were purchased many years ago at a very low price, and where the rainfall conditions allow the irrigating value of sewage to be taken advantage of, in a way that does not exist in our eastern or central states. The increment of land value alone at Berlin seems to justify a continuance of a method which is expensive at best.

The consumption of water percapita in Berlin, as compared with that in the cities of the United States, has quite a little to do with that problem. The amount of water consumed in Berlin is only about 30 gallons per capita as compared with 200 gallons and more found in many of our American cities. That has a good deal to do with the cost of intercepting sewers, pumping stations, and works for delivering the sewage to the farms. And it requires a much smaller area per capita in European cities than would be required in our American cities.

Chemical precipitation works in 1889, had been recommended for adoption in Providence, and those works were built after an interval of some 14 years, put in service in 1901, following the recommendation for adoption in 1887. Their

purpose was to eliminate sewage mud from the Providence Harbor, and to prevent the foul decomposing conditions there found.

That method of chemical precipitation at Providence, was continued until a year or two ago, when it was superseded by plain sedimentation and sterilization of the sewage, for the purpose of protecting the shell fish layings in the Providence River below the outfall from the treatment works in the deep water at Field's Point.

At Worcester, under orders of the court as the result of litigation on the part of the riparian owners in the lower Blackstone River, the City of Worcester about 1889 started to build chemical precipitation works, which were completed in 1891. Those works were enlarged a few years later, and are in service today to treat some of the sewage, which, for the most part however is now being treated in works of more modern, economical and efficient design. The few little chemical precipitation plants around Coney Island, and some of the beaches of greater New York, at Canton, Ohio, East Orange, New Jersey, and a little plant in the Mystic Valley just outsde of Boston, have all been abandoned.

1425 It is a fair general statement to say that the chemical precipitation method has no standing today in this country for disposing of sewage as regards elimination of sewage nuisances, except perhaps for some small problems where there are complicated trade wastes. Its day has come and gone, and I think that statement applies also to the large European cities generally speaking. It is certainly true of London, where this method of chemical precipitation received its great impetus in the late eighties.

Since the days of 1889, there has been quite a substantial advance made in treatment works for sewage, that has come in as the result of the pressing needs of some communities located on small streams, where the dilution method could not be satisfactorily applied in order to remove a nuisance in those streams.

Continuing the developments of the art since 1890, I will say that various methods have come up for the consideration of the solution of sewage treatment problems. From about 1895 to 1900, the so-called single story septic tanks were in vogue. Their purpose was to remove the solid sewage filth, and allow it to become septicised, and in early days it was assumed all solid sewage filth could be liquified, and gasified by bacteria. Practical developments have shown that this was not feasible.

More than that, the practice with large cities has shown that very severe complications in point of nuisance have been brought about, as the odors from septic tanks have arisen.

Recently, septic tanks of the single story type, built so frequently a dozen years ago or so, have been practically abandoned for all large municipal projects. Within the last year, there has been put in service at Atlanta a two story tank, a settling and septic tank, which has proved to be of much practical benefit, according to the data now available. This is the method of clarifying sewage that has superseded both the chemical precipitation of 20 years ago and the single story septic tanks of a dozen years ago.

In regard to methods of oxidizing those portions of sewage which are either in solution or will not settle in settling tanks, there has been a radical change in the art from 1889, when sewage farms were almost exclusively used.

First there was developed in Massachusetts the intermittent sand filter, where sewage was applied to large areas
1426 of porous sand found in place in sections where glacial drift formation was noted. In the central, western and southern states, that method had no footing because the porous sandy deposits did not exist in place, and the method was found to be too expensive when sand beds had to be built artificially.

Next, there came, about 1900, the so-called contact bed in which beds of stone were filled with sewage, and allowed to have the pores stand full of sewage, for a few hours when

the bed was drained and allowed to have its pores filled with air. That method was found to be prohibitively expensive for large projects, and its use today is confined to small communities in residential districts, where the effort is to minimize the odor question.

In places where water cannot be made available for oxidizing clarified sewage, so as to prevent sewage nuisances, it is found that the so-called sprinkling filters are the best means of making sewage stable or non-putrescible. By that I mean the treatment of sewage, so that it will no longer putrify after treatment, and after standing for an indefinite period. These devices are large beds of stone, perhaps one to three inches in diameter, and six feet or more deep, and on to which the sewage is thrown in the form of a spray from numerous spray jets, spaced perhaps ten feet apart, over the surface of the bed. The practice has shown that these devices will produce a non-putrescible effluent; but it has also been found, at Columbus and elsewhere, that unusual care must be taken for large projects, to keep the sewage in a fairly fresh condition, so that very serious odors will not arise in the neighborhood of the sprinkling filters. These odor factors have not been encountered in the smaller plants, and in a large scale, the art now shows means of guarding against the odors by keeping the sewage well aerated, and thus arresting putrefaction of the liquid before it meets the sprinkling filter beds.

In the general developments of the art of sewage treatment works, practice has shown that it is much more expensive to build and operate these works on a satisfactory basis than was anticipated a few years ago. In fact, the experiences of the past year or two indicate clearly that projects now in service involve considerably larger sums of money than the earlier estimates indicated.

One other factor I should mention in the art of sewage treatment works, and that is the sterilization of sewage to attempt to destroy disease germs.

Nothing was known of sewage sterilization on a practical scale until about 1906. It was then tried at Red Bank,
1427 New Jersey, to apply hypochlorite of lime in settling tanks to sewage with a view to reducing the number of disease germs in the liquids that were sent out in tide water, in the vicinity of shell fish layings. There have been a number of projects recommended for the sterilization of sewage, but so far as I know there is no instance where large cities have made public any records as to experiences in the systematic sterilization of sewage. The nearest approach to it is at Providence, that I have already spoken of, and where they have abandoned chemical precipitation and started out on a tentative scheme of using their tanks to settle the sewage and to apply sterilizing processes in the interests of shell fish layings in Narragansett Bay.

I have been told also that recently the City of Toronto is attempting to sterilize its settled sewage before discharging it into Lake Ontario.

With regard to the dilution method, the greater attention given to sanitary matters in various parts of the country has shown that it was applied in earlier years with many shortcomings. By that I mean that sewer outlets were built into water courses to a very unsatisfactory degree. There are many American rivers and lakes where sewers reach only to within 100 feet or so of the water's edge, and show a pollution which has given rise to offensive conditions that do not exist or would not exist if the sewage had been well mixed with available water for dilution.

It is also found in some places that sewage has built up sewage banks or sludge deposits, which could be remedied with a little care.

So in brief, the dilution method in my opinion, as the result of careful study of the various engineers, now applying it on a more rational basis than in earlier years, is now on a firmer basis than ever before.

It is true however that it is suffering, in the public mind at least, from the poor reputation it got in earlier years, when it was applied in a very inadequate and haphazard fashion in a great many cities, with attending nuisances as to odor. Today I believe it is entitled to far more consideration than ever before, and I think that engineers in approaching these problems will give it in many cases more careful consideration than they would have done a short time ago, when it was not so clearly appreciated as to what the conditions were, under which it could be used, and take advantage of its economy and allow local nuisances not only to be eliminated, but to allow them to be eliminated in a way that they would not be transferred to other neighborhoods.

1428 The ratio of dilution, that is to say 3.33 cubic feet per second per thousand population, that is prescribed by the act under which the Sanitary District of Chicago is organized, in my opinion is as low a ratio as it is feasible to employ, when consideration is given to the domestic sewage of a community.

If I were to consider any change in this ratio, I should be disposed to increase it. That ratio makes no provision for trade wastes; and if trade wastes were to be considered as well as the domestic sewage, I believe this ratio should be increased.

I have looked into this matter with considerable care; have been down the length of the Drainage Canal, studied the records on may occasions. I am making this statement now with respect to conditions as applied to the Chicago Drainage Canal.

I take trade wastes to mean those products which arise in large industrial establishments, for instance tanneries, packing houses and slaughter houses, where the wastes are removed by water carriage, are substantial in quantity, and are entirely different from what you would get in sewers, which drain the ordinary residential community, with the wastes that would come from business blocks, commercial en-

terprises and small manufacturing establishments where the wastes that went into the sewers were merely nominal in amount. As applied here particularly to the Chicago problem, it relates essentially to the waste coming from the Stockyards district and to the tanneries and to the other establishments along the North branch.

Now, in this problem, I have given no consideration to the trade wastes item. The reason for that position is that the disposal of trade wastes is a matter which applies with equal force, whether on the one hand you are considering the dilution method for the local problem, or whether there are considered treatment devices for disposing of the sewage other than by dilution methods.

In other words, it is an item which appears on both sides of the equation in these dilution projects which I have studied; and being the same item on each side of the equation, it properly drops out of consideration.

1429 I might further say that it is my understanding that the Drainage Canal here was projected on the basis that trade wastes were not to be a factor ultimately in dilution ratios, or in other aspects as regards sewage disposal. It is a fact, however, that trade wastes have gone down the Drainage Canal, as an incident to the period during which the volume of domestic wastes has not required the amount of diluting water equaling the capacity of the channel.

I understand further that in the Department of Engineering of the District, there has been established a division, the purpose of which is to study various methods for treating trade wastes, without, however, any consideration, so far as I know, of the financial arrangements under which such treatment methods would be applied.

In my opinion, the protection of the Chicago water supply is secured in a more simple, effective, economical and therefore better way, than could be secured by any other means of treating the sewage than by the present method; and that applies to the art of 1889, and also to the art as known to-

day, in the matter of sewage diversion and sewage treatment.

A reduction to 4,167 cubic feet per second in the flow of lake water through the main channel and its adjuncts would create a profound and unfavorable disturbance in the fundamental principles upon which this project was designed and built. They would relate to several factors, which I will speak of in turn.

First, a flow of water from the lake of 4,167 seconds feet would defeat the main purpose of the channel, which is to secure at all times a reversal of flow of the Chicago River, in order to protect the water at the intake cribs of the Chicago water supply.

In other words, at times of very heavy rainfall, there would be a reversal of flow of the Chicago River carrying the
1430 river water and considerable sewage out into the lake, such as was the condition of affairs prior to 1900. That reversal would occur on a good many days in the course of a year; at least ten in the ordinary year, and a much greater number than that during years of abnormally high rainfall, or having periods of unusually high rainfall.

I wish to point out that even on the assumption that at times of heavy rainfall the flow down the channel would not be limited to 4,167 seconds feet, that, in a practical working way, this does not modify my statement above as to inability to secure a reversal of flow of the Chicago River such as is necessary in order to protect the Chicago water supply. The reason for that is that it takes a good many hours, half a day or so, in order to change the regulating works at Lockport so as to increase the volume of flow in the vicinity of the Chicago River down into the main channel and into the Des Plaines River. It is this lag of half a day or so, which in my opinion would prevent the practical operation of the Drainage Canal in times of storm flows, so as to secure the protection that now comes from the present method of operation with respect to preventing sewage getting to the intake cribs.

A third aspect of the proposition, assuming 4,167 seconds feet diversion from Lake Michigan water through the main channel and its adjuncts, would force to consideration other means of treating the sewage, which now is disposed of by the dilution method. That flow corresponds to the legal minimum ratio of dilution for about 1,250,000 people. Obviously the domestic sewage from a population in excess of that figure would require treatment works, or other means of eliminating sewage. This last proposition involves two aspects: One is the feature of the dilution of sewage, so as to prevent putrefication of the flowing sewage; and in the second place, with this assumed reduction in the flow of Lake Michigan water, the velocities in the waterways of the 1431 channels, main channel, Chicago River and the various appurtenances would be reduced so that the solid sewage matters would become stranded to an extent where sewage mud banks would arise, putrefy and produce seriously offensive odors.

To my thought, it means that with this reduced flow of lake water it would be necessary to settle all of the sewage so as to keep the sludge out of the waterways, as well as to provide means of protecting the water supply through the sterilization of all sewage. And it would further mean the use of sprinkling filters, or other devices, for rendering stable and non-putrefactive the flow of sewage in excess of that which could be properly diluted with this 4,167 seconds feet of lake water.

In the event that the flow of lake water were reduced, or limited to 4,167 cubic feet per second there are two styles of procedure, or two projects which could be adopted for protecting the water supply of Chicago and eliminating sewage nuisances.

The first of these (which I will call A) would involve the collection of the dry weather sewage flow and the first flushings of storm flows, after they pass through settling tanks and apply them to sprinkling filters, so as to render the sewage non-putrescible.

The sprinkling filters should be built to take care of the sewage flow from such portion of the population as could not allow its settled sewage to be adequately diluted by the 4,167 seconds feet of lake water. It would be necessary in protecting the water supply to sterilize this flow of sewage after its treatment by settling or sprinkling filters, or both; and it also would be necessary to sterilize the storm overflows at times of very heavy rainfall. The reason for this sterilization would be that if it were not sterilized some of this treated sewage or storm overflow, or both, being present in the Chicago River and its tributaries at the beginning of heavy downpours, would be sent out into the lake at times. Therefore, to be on the safe side and reasonably to protect the water supply, it would be not only necessary to settle or filter the sewage to guard against nuisance day by day, but it would also be necessary to sterilize these liquids to protect the water of the lake at the intake cribs.

1432 There is a second method of procedure (which I will call B) which would be a project involving, in the first place a system of separate sewers throughout the district for collecting the household wastes. That would mean a new set of sewers on all the streets where sewers now exist. It would mean that the rain water falling on the streets and roofs and various areas, yards, vacant land and parks, would reach the water courses through the present system of sewers; and that all house connections for all the properties of this district would be disconnected from the present system of combined sewers and shifted over to the proposed system of separate or sanitary sewers. The flow of such a proposed system of separate or sanitary sewers would then be treated by sedimentation and filtration to secure a product which would not produce putrefactive conditions in the channel, and this flow would also be sterilized.

Under this arrangement, the storm water which would reach the water courses through the existing system of sewers would go there without any treatment of any kind.

As these two projects have been developed, it is necessary, first, to state how the sewage would be brought to various places for treatment.

I will speak first of project A, in which the flow of sanitary sewers would be through the existing present combined sewers. Speaking generally, there would be intercepting sewers, which would run along the margin of the Chicago River, and at some other points, picking up the sewage from the lake front. These intercepting sewers would receive the settled sewage which would flow from the sewers as they exist to-day. By that I mean that the sewage flow would be led into settling tanks before it discharges into the water courses. This ordinary dry weather flow and the first flushings of storm water would then pass from the tanks to intercepting sewers. These intercepting sewers would lead to sprinkling filter sites in most cases, where the sewage, with some intermediate pumping, would all be lifted at the end of the intercepting sewers on to sprinkling filters, where it would be applied to beds of stone through various spray jets.

Speaking generally now of locations—I am looking at the map marked Fuller Exhibit 1, November 17, 1913—I will call attention to the fact that along the north branch, for instance, intercepting sewers would be built from Kinzie street on either side of the north branch to a point above Fullerton avenue, where the conditions would allow sedimentation tanks to be built. There are some sixteen sedimentation tanks
1433 which would be required along the north branch north of Fullerton avenue. The flow of sewage from these settling tanks would be into interceptors, which would lead on either side of the river to about Lawrence avenue. Thence they would unite in a single interceptor built, leading to a proposed sprinkling filter area, just north of the city limits between Devon street on the south and Touhy avenue on the north. This area lies immediately west of the present north shore channel.

These intercepting sewers would be built of a capacity of about 900 gallons per capita, with a population estimated

DESCRIPTION OF BOUNDARY.

as of 1930 for the various areas tributary to these respective sewers.

There are, besides this so-called Lawrence avenue project, for treating the sewage north of the Chicago River, three other projects. The second one, spoken of as the West Side project, would involve the collection of sewage from the Loop District, and an intercepting sewer which would run along the west bank, or near the west bank of the Chicago River, to the vicinity of Western avenue. There the settled sewage, which at various outlet sewers would pass through settling tanks and into this interceptor would be lifted from the interceptor to settling tanks located between Western avenue and Kinzie avenue beyond the Bridewell; and thence the sewage from the western portion of the city in the sewers now existing and located north of the main channel would likewise return to this main settling tank.

Sprinkling filters, so far as required, would treat the settled sewage from this main west side plant at an area located north of the main channel, south of 39th street, and between South 64th and South Harlem avenues. These sprinkling filter sites in all instances are colored brown on this map.

The third main project, spoken of here as the 39th Street Project, would receive the sewage from the various sewers tributary to the present 39th Street Pumping Station. There on the lake front, settling tanks would be located, the flow of which would be pumped through a conduit which should receive also settled sewage from various main sewers in this area lying south of the Chicago River, excepting the Loop District, and south of the main channel. This settled sewage would be delivered for treatment in sprinkling filters to an area immediately south of that which I have previously
1434 described, that is south of the main channel, and lying between South 64th avenue and Harlem avenue.

There would be needed in this instance several pumping stations and settling tanks for the Stock Yards District and for the various sewer outlets now discharging into the river

or channel, and not tributary to the main pumping station at 39th street.

The fourth project, spoken of here as the Calumet Project, would involve an intercepting sewer starting in the vicinity of the 95th Street Pumping Station, taking the flow from the various centers of population in the Calumet District and leading to sprinkling filters lying just north of the Calumet River, south of 130th street, and lying immediately west of Cottage Grove avenue extended south. On this system of intercepting sewers, there would be settling tanks at the outlets of the various sewers and a number of pumping stations, all of which will be detailed in the estimates which I will consider later on.

On this map, the intercepting sewers are marked in red showing their location, and also with an arrow indicating the direction of flow.

The sewage pumping stations, at points where it is necessary to lift the sewage flow along the line of the interceptors, are shown with black circles, and the same black circles are used to indicate the pumping stations needed for lifting the sewage at each of the respective sprinkling filter sites. The sedimentation and disinfecting plants are shown in yellow with a heavy black margin around the area, and as I have already stated, the sprinkling filter areas are shown in brown.

I should explain that at all of these settling tanks, the flow of the sewers in excess of 900 gallons per capita for the 1930 population would have disinfection or sterilization plants where such excess storm flow would be thoroughly disinfected.

1435 Now, proceeding to what I have called the other project, Project B, the various treatment works would be located at the same areas as I have just described for Project A. The intercepting sewers, however, would be smaller because they would deal only with the domestic wastes and not receive storm flows. They would be, roughly, half of the capacity of the interceptors of Project A. The pumping stations would

also be smaller in size, on account of having no storm water to deal with.

I have assumed that the settling tanks, sprinkling filters and the interceptors, in point of location, would all be located precisely as in Project A.

By Project B, there would drop out of consideration, however, the disinfecting plants as regards storm water flows; but the treated sewage would in all cases be subjected to sterilization.

One further word about the sterilization should be added, and that is that where the sewage is subjected to treatment in sprinkling filters, the sterilization plant would deal with the filtered sewage after it had been subjected to a secondary sedimentation.

In those cases where the sewage is not passed through sprinkling filters, the disinfection would take place at the primary settling tanks, and adjoin the works for sterilizing storm overflows in Project A.

This map marked Fuller Exhibit 1, on page opposite, shows also a small project marked here the "North Shore Project," wherein is shown a system of intercepting sewers beginning in Glencoe near the northern district boundary line, coming through Winnetka, Kenilworth, down to Wilmette; there showing a pumping station and small treatment works for a population of 55,000 people estimated as of 1920.

In regard to the collection of the sewage flow from the present sewers discharging into the various water courses, I should state that in these intercepting sewers and appurtenances arrangement is made for areating the sewage. The purpose of that aeration is to prevent putrification taking place such as is found in a great many outfall sewers of large cities, owing to the age of the sewage. Now, to prevent and offset the putrification, which is due to bacterial processes taking place as the liquid flows in the sewer, provision is

made in these projects for pumping in air so as to keep the decomposition on an oxidizing and not on a putrifying basis.

With respect to the population, it will perhaps be more explicit to repeat a word or two, and say that these intercepting sewers for delivering the sewage flow to settling basins, 1436 sprinklers and treatment works, the design has been based on the assumed populations of 1930, namely 3,500,000 people. With respect to the treatment works, this is including the filters, settling basins and sterilizing arrangements, the population has been assumed as of the date 1920. On that date, the estimates of population show for the city a population of 2,900,000. In fitting these different projects to a population basis, there has been some little latitude used and there has been included the population of the Calumet District on the south and the North Shore district on the north.

The population provided for in my estimates is: Within the city, 2,900,000 population; outside of the city limits, in District 14 on the west side, 133,000; 21,000 outside the city limits in the Calumet District, and in the North Shore District 55,950. The latter figure includes Evanston.

Now, the summation of all of these different populations assumed to be provided for in the respective treatment works amounts to roughly 3,000,000. I have assumed in my estimate that that would be equivalent to what would be served by 10,000 seconds feet flow in the main drainage canal, equal to 3,000,000 people.

I am aware that in making estimates of future growths of population in different districts there are bound to be some discrepancies, and these aggregate figures are rather more liberal than should be made for the respective individual treatment plants.

I think next I will outline briefly the particular devices which it is proposed here to use in settling and filtering the sewage, and in sterilizing it; and refer roughly to what in practice elsewhere these particular devices have accomplished in the nature of improving the hygienic character of the

sewage, and with regard to the bearing which the works would have upon the elimination of sewage nuisances.

The settling tanks would be built of the two-story Imhoff type. By that I mean that there would be large settling tanks built with their flow line roughly corresponding to the flow line in the existing sewers. They would have a depth of some 25 feet, say, and be in two stories. In the upper compartment, the sewage would flow through the tanks for a period on an average of two hours. The increase in the cross-section of that settling compartment with respect to the size of the sewer so checks the velocity down to half an inch per second or so, with the result that there are deposited the coarse matters in the sewage.

In the bottom of this compartment is a slot or opening, through which the solid matters would pass to a large
1437 chamber beneath. This lower chamber is called a digestion chamber, and in it the solid matters would be allowed to accumulate for perhaps six months or so. During this interval bacterial decomposition would intentionally be directed and encouraged, so that it would gasify, putrify and allow the bacteria to eat up all of the unstable organic matters. Much of this solid matter would be changed to liquid and gaseous substances. The result of this is that the sewage sludge would become septicised or eaten over by the bacterial life, so that it would be taken out in a substantially inodorous condition.

This wet sludge from the lower compartment would be removed at intervals through a pipe, and applied to little thin beds of sand and gravel; and it so happens that the sludge as removed contains much gas. This is of importance, because when it is removed and applied to these straining beds or sludge beds, the gas seems to lift the solid matter to the surface, and it allows the liquid from the bottom to pass down through the sand and gravel of the bed to which it is applied. In the course of a week or so this septicised sludge has been so freed of water that it is spadeable, and can be

shoveled into containers for its removal to any convenient place to be used for filling, or to be stored in a spoil bank.

At these settling tanks along the various sewer outlets going into the water courses, arrangements would be made whereby the sewage flow passing through the tanks would be limited to three times the dry weather flow, or to 900 gallons per capita daily. The storm flow in excess of that quantity would not pass through the regular settling tanks, but would be subject to sterilization. By sterilization, I mean that there would be added to the storm flows liquid chlorine sufficient to kill the disease germs in the liquid and upon the exterior of particles of suspended matter. Sterilization is, of course, not effective in killing the germs in the interior of particles of suspended matter.

These tanks for purposes of sedimentation would allow the removal of some 90 per cent or so of the particles which are capable of settling. They do not of course affect at all those soluble matters in the sewage, such as urine, nor the fine particles of fecal matter, or substances of other origin which are so fine that they will not subside. That is, the non-settling solids and the soluble matters in the sewage pass through the settling tank and on into the intercepting sewers.

In the course of six or eight hours or so, sewage will become, under ordinary conditions in large cities, putrifying, and productive of foul odors to an objectionable degree.
1438 These intercepting sewers are supposed to carry sewage which has its content of oxygen not depleted; and the oxygen supply is assumed to be replenished by pumping air at intervals into the flowing liquid in the intercepting sewers. The quantity is, in accordance with various tests at New York, roughly, one-tenth of a cubic foot of air to one gallon of sewage.

In those cases where the settled sewage must be filtered, that is for all projects other than the West Side Project, the settled sewage will flow in these intercepting sewers and be pumped at the respective filter sites onto the sprinkling filters. I should say that for the West Side, I have assumed that

the settled sewage from the central west side area, from the Loop District and the floating population in the Loop District of some 300,000 people, that that settled sewage could be adequately diluted by 4,167 seconds feet flow of lake water, so that it would not be necessary to filter it.

The removal of organic matter by sedimentation is taken to be roughly 25 per cent on an average, as compared with the organic matter in the raw material. To reduce the organic matter of the settled sewage to a point where it will not putrify in the water courses, it is estimated that there would be required one acre of sprinkling filters for 12,500 population.

These sprinkling filters, as I have already stated, would be large beds of stone, of a size ranging from one to three inches in diameter, about six feet deep. To these filters, the settled sewage would be applied from a series of sprinkler nozzles, spaced roughly ten feet apart. The sewage would then be thrown as a form of spray such as from a lawn sprinkler over the surface of the bed of stone. These sprinkler filters operated at this rate will produce an effluent which will not putrify after there has been removed from it some suspended matters which are released from the bed in an irregular way.

To clarify this filtered sewage, these projects provide for secondary settling tanks holding about one hour's flow, and of about the same size structure as the primary settling tanks, but of one-half size for a given sewage volume.

This sewage sludge would be similarly strained on sludge beds to remove the water, so as to get it in a spadeable condition for removal to a sludge bank, or any other convenient way of disposal. The sludge has somewhat limited value for fertilizing purposes, and in some cases in Europe it is taken away free of charge by the farmers of the neighborhood.

I have assumed that it would cost some 50 cents a yard
1439 to get rid of this sludge, and that it would not be feasible to dispose of it to farmers.

Wherever the dry weather flow of sewage is subjected to filtration the sterilization process would be applied to the effluent after it leaves the filters, and not to the settled sewage before it reaches the filters. In the West Side Project where filters would not be needed with the present assumed volume of lake flow, the sterilization process would be applied of course to the flow from the primary settling tanks.

In the matter of efficiency of sprinklers, I would say that they will reduce the organic matter in the sewage some 70 per cent or more, and in connection with the oxygen present in the filtered sewage, they will produce a stable liquid which will not putrify upon exposure to sunlight and the air, for a long term. There are times when these beds unload their solid matter, when perhaps that would not be literally true; but generally speaking these beds, in practice at the rate here indicated would produce a liquid which would not give trouble from putrifaction.

The removal of bacteria by the sprinkling filters would probably range from 80 to 90 per cent. The liquid would be substantially free of suspended matter. The sterilization of the filtered sewage would have for its purpose, of course, the destruction of disease germs to the extent of the 10 or 20 per cent remaining in the filtered sewage as compared with that appearing in the raw sewage.

As to storm water flows, the liquid coming from the streets contains a good deal of organic matter, and would probably call for as much as 70 pounds of liquid chlorine to the million gallons. For the ordinary settled sewage coming from the primary tanks, I assume it would take some 50 pounds of liquid chlorine to a million gallons. For the filtered and settled sewage I have assumed that about 10 pounds per million gallons would be sufficient.

As to what sterilization will accomplish in point of removal of disease germs, I should say that the removal would amount to 95 to 99 per cent, depending upon the success with which the applied quantity of liquid chlorine was adjusted to

the particular organic content of the liquids flowing, and recognizing the variation in such flow, and in their strength from time to time.

In the matter of pumping stations, these projects for the
1440 treatment of the sewage would involve the operation of the present pumping stations for sewage flows at 39th street, Lawrence avenue, 95th street and elsewhere. They would also require some intermediate pumping along the line of the interceptors, at settling basins and at each of the respective filter plants it would be necessary to lift all the flow, in order to produce a head sufficient to distribute the sewage to these various sprinklers scattered over the surface of the filter bed. There would have to be a head at the nozzle of some six to eight feet, as well as to lift the sewage up to the elevation of the nozzle itself.

In regard to the question of odors and nuisances, I have already spoken of the great importance of preventing such conditions as have arisen at Columbus and Baltimore, where the sewage has become highly putrefactive before it reached the treatment works. That would be accomplished by the aeration that I have described.

In regard to the sprinkling filter sites, I have outlined certain locations which have been used as the basis of these studies. It is not necessary to treat them precisely at the areas indicated on this map marked Fuller Exhibit 1, but those approximate areas, however, are convenient and suitable; and in these instances are entirely reliable for the purposes at hand. These different filtering site areas cannot be limited to the immediate ground which would be occupied by the structures. It is found that in these beds there will grow flies and various forms of animal life, and it is necessary for that reason to purchase land which would keep other property owners from living immediately adjacent to the beds.

There is also the item of odor, which is not very serious if the sewage is kept in this fresh condition that I have spoken about with respect to aeration.

For instance at Reading, Pennsylvania, where the sewage is fresh, it is a mountainous town and high velocities obtained in all cases, the odors are rarely if ever noticed more than 300 feet away. Most sprinkling filters, however, are apt to develop an odor, in the case of large plants for a quarter of a mile; occasionally in some plants it is extended much further than this.

In these estimates made in developing this project, allowance is made for the purchase of land one-quarter of a mile in extent around the entire outer periphery or building line of the proposed works.

In regard to the question of odor around the settling basins, I do not believe that there would be anything serious encountered there, nor would the flow of storm water
1441 treated with liquid chlorine be objectionable in the water courses. It is conceivable, however, that lack of care might produce an excessive application that might not be present except for a very short time.

That, I believe, covers in outline the main features of the best methods now available for building treatment works to clarify sewage, to eliminate the stranding of sewage solids, and putrefaction of mud banks, to take the sewage after settlement and where there would not be water available for oxidizing it by dilution, then subjecting it to the oxidization in sprinkling filters and finally in sterilizing all of these flows so as to destroy objectionable bacteria to the extent of say 95 to 99 per cent of those contained in the original sewage.

This residual small percentage, as I have already explained, cannot be reached by sterilization or any other process, on account of some of those germs being located within the interior of tiny little particles of fecal matter, where the chemicals will not have access. These treatment works are the best that can be applied to problems of this kind, as the art of sewage treatment is known today, both in point of theory and practice.

In regard to the pumping stations, I might add a word and say that they are all assumed to be centrifugal pumps, steam driven, and are assumed in the estimates to be strictly in line with the installations of sewage pumping machinery in the district here in Chicago, and in other large cities. The equipment, as I have said, provides for handling the sewage at a number of points along these interceptors, and in pumping all of the sewage going onto the sprinklers.

That approximate figure of population in 1920, has shaped itself in these estimates by virtue of the fact that the population then existing in the city and in the outlying areas within the Sanitary District would roughly equal the diluting capacity of a 10,000 seconds feet flow of lake water down the main channel. It also represents the best judgment of those familiar with the details, according to my information, of the past growth and the increments in growth leading to proper and reasonable conclusions as to what the 1920 population may be.

My own purpose was largely in getting at a figure as to scope of project which would allow a comparison to be made of the treatment works for a 3,000,000 population which has come into this project, and my reflections in connection
1442 with the 10,000 seconds feet flow, when treating the population at the legal minimum dilution ratio of 3.33 seconds feet per thousand.

I have estimated that it would cost for construction purposes to build Project A, $71,365,866. The annual operating expense and depreciation I estimated at $5,116,057. I have capitalized this annual charge for operation, maintenance and depreciation at 4.25 per cent, and have added it to the investment cost. This makes a sum of $191,742,866. That is the sum which it would cost this district to take care of the sewage by Project A, for the population estimated to exist in 1920, roughly 3,000,000 of people.

For Project B, the investment cost I place at $131,229,707. The annual cost of operation, maintenance and depreciation,

I place at $4,524,952. Capitalizing the latter sum at 4.25 per cent, and adding it to the investment cost, there is obtained $226,970,647, as representing the cost to the district of treatment works for 3,000,000 people by Project B.

Under Project A, to provide treatment works corresponding to a population which would be taken care of by a lake
1443 flow of 12,000 seconds feet, the investment cost would be $85,000,000. The annual operating maintenance and depreciation cost would be $6,102,000. Capitalizing the annual cost and adding it to the investment, there would be obtained $230,000,000. The corresponding figures for treatment works of a capacity equal to that which would be taken care of by 14,000 seconds feet flow of lake water would mean, by Project A, an investment cost of $100,000,000, an annual operation, maintenance and depreciation item of $7,260,000. The sum of the investment and capitalized operating expense would be $268,000,000.

I should state that these figures which I am reading are round figures, obtained with a slide rule. They are not figured to individual dollars and cents.

By Project B, the investment cost of treatment works, with separate sewers to provide for a population equal to that which would be taken care of by 12,000 seconds feet flow of lake water would be $157,000,000. The annual cost would be $5,40,0000. Capitalizing the operating expense and adding it to investment, the total cost becomes $270,000,000.

The corresponding figures by Project B, for treatment works equivalent in population served to that for 14,000 seconds feet flow of lake water becomes for investment cost $183,000,000; the annual cost would be $6,300,000. The sum of the investment plus capitalized annual charges would become $316,000,000.

I should perhaps state with regard to Project B, one or two points that I think I briefly touched upon in my preceding answer; and that is this Project B deals with no storm water sewage at all, no street wash, but assumes a complete

new system of sanitary sewers which would deliver to settling basins the sanitary wastes of the community. That settled sewage would pass through interceptors with areating arrangements onto sprinkling filters, all in substantially the same way as in connection with Project A. The intercepting sewers, however, would be of about half size. The pumping stations would be somewhat smaller. There would be no
1444 sterilization of storm flows; it would go directly into the river without treatment through the existing sewers. The settled sewage, filtered sewage, would be sterilized.

I should say that eight years would be a fair estimate for the period of active construction. I have placed the time at ten years, assuming that conditions would be favorable in all respects with regard to securing funds with which to build these works, and to get the necessary legislation, enabling acts, and condemnations of lands and rights of way.

I could point out for instance that at Providence it was determined in 1887, to build chemical precipitation works, but they were not put in service until 1901. That period
1445 in the interim was required for financing and building the necessary intercepting sewers and treatment works and in adjusting delivery of sewage to those new structures.

In Boston, the original main drainage works were recommended in 1875 for collecting the sewage of the old city of Boston and delivering it to Moon Island for discharge on the outgoing tide. Those works went into service in about 1884.

The Washington works for intercepting the sewage of Washington City and pumping it after some screening into the Potomac River below Washington were recommended by the Commission appointed by President Harrison in 1889. Those recommendations by the Commission were made in the early part of 1890. I think it was 1908 before those works were completed and put in service.

In the Passaic Valley Project, in New Jersey, opposite New York City, the first recommendations there were made in 1897. The matter was reviewed by a State Sewage Commission again in 1901. There was an enabling act passed in 1903. It was in litigation in point of constitutionality until 1907, and the project in its present form was outlined by Hering & Fuller, in 1908, and the construction work was started in 1912, about a year ago, and it is still subject to injunction suits and various vicissitudes of litigation, and including an injunction suit brought in the United States Supreme Court by the State of New York with respect to discharging this sewage into the upper New York Bay.

The Charles River Dam project in Boston was active in my days there in 1891. That relates to building a dam across the Charles River near the old Cragie bridge, and preventing the exposure of the tidal flats on the Boston and Cambridge sides of the river, and in building intercepting sewers along the water front on each side to send the sewage down to points beyond or outside of Boston Harbor.

Those works were the subject of many legislative investigations, particularly a very exhaustive one made by Mr. John R. Freeman in 1903. The works have been in service I should say about three or four years, so that I think experience very abundantly shows that actual periods required for getting legislation and in getting financial programs adjusted, getting works that will not be made the subject of too many legislative inquiries and investigations by Citizens' Committees, I think all of those things taken into account make the period very much longer than the actual designing and construction calls for.

I doubt whether any of them exceeds $15,000,000 in in-
1446 vestment as compared with $70,000,000 here for Project A, and $130,000,000 for Project B.

Project A would involve tearing up streets along the lines shown here in red ink on this map marked Fuller Exhibit 1. It would cover a good many miles of streets in the

vicinity of the water courses of the north branch, the
1447 main Chicago River from 39th street over beyond the Stock Yards district, to a point where 39th street meets the Drainage Canal; also down through the Calumet District as shown in this plan.

In Project B, there would be involved the tearing up of every street throughout the district, in order to build the sanitary sewers in it to parallel the existing sewers. It would not only mean tearing up every street that is now paved, but it would also mean lateral house branches from the street sewer out to the curb line under the sidewalk to the property to the building line.

It would encounter, of course, a good many underground obstructions, in the nature of interference by existing utilities, water mains, gas mains, electric light conduits and telephone conduits, etc.; also make a decided impression on street pavements; involve considerable care in maintaining trolley lines in service during construction periods.

(Mr. Fuller corroborated the testimony of Mr. Wisner as to the conditions at Chicago and with reference to the effect of the Sanitary District diversion works.)

Asa E. Phillips, a witness for the defendant, (Rec. Vol. III, pp. 1516-1533; December 12, 1913):

Resides at Washington, D. C.; civil engineer; graduated from civil engineering, Lehigh University, 1893; had charge of the preparation of the plans for construction and operation of the sewage disposal system of the District of Columbia, covering a period of more than fourteen years; for the last seven years superintendent of the sewer department of the District of Columbia; made special studies of modern development of sewage treatment; connected in an advisory way with the Passaic Valley work.

The witness further testified:

City of Washington uses the dilution method; sewage is collected at certain points, then pumped from the low level to a higher level sewer by means of which it is discharged into the Potomac River mid channel below the city. The Washington city sewage disposal was planned and recommended by commission of engineers appointed by President Harrison in 1889, consisting of Messrs. Rudolph Hering, Frederic P. Stearns and Samuel M. Gray. Total cost of the work was $5,000,000. They were not completed until 1907. A modern filter plant has been installed for the water supply.

In a broad sense, artificial sewage treatment plants are not used. In something like eighteen cities having a population of over 300,000 people, the disposal of sewage is entirely by dilution, with the one exception of Baltimore, which has recently completed a plant but has only partly operated same to date. In fourteen cities having a population of over 150,000 and less than 300,000, there are treatment works at Providence, Rhode Island, Columbus, Ohio, and Worcester, Massachusetts. The purpose of these treatment plants is generally to prevent a nuisance in streams into which they discharge. One of the older works of Providence, Rhode Island, was put in with a view of preventing the oyster beds in the Providence River below the point of discharge from being polluted. The same is true as to the works at Baltimore.

Looked at from the point of view of practical results up to date, none of these works have accomplished what would reasonably be supposed to be their complete function. In every case, they discharge either an effluent that does not have a degree of purification such as to prevent the streams from actual and dangerous pollution, or they operate intermittently, and intermittently throw a load of sewage directly into the streams, or discharge the sludge from the treatment works at times into the streams.

In the comparison between what is accomplished at these works and what is accomplished at other works using the method of dilution where reasonably uniform and con-
1522 stant results are obtained, practically unchangeable except due to the variation of season and of temperature, these artificial treatment works have not been successful. Some qualification ought to be made as to this, in the case of the new works at Baltimore which, while completely constructed, handle only a very small portion of the sewage, and with regard to these works they have developed just as the works at Providence developed, very serious local nuisances, which are involving lawsuits. And at Baltimore, a very great reliance, even by the engineers in planning the works, has been placed in the effectiveness of the purification by dilution, that would be accomplished in the travel through the arm of the Bay in which they discharge.

In the case of the other works, having only in view the prevention of the gross pollution of small streams, such as the new works at Atlanta, there is no very serious problem such as the protection of the water supply, involved.

The works at Providence, chemical precipitation works, designed to protect the oyster beds from pollution, have been substantially abandoned, and the works there today, with the exception of some sedimentation and some attempt to disinfect the sewage, are substantially, pure and simple, works of dilution.

The abandonment of older processes, though comparatively new themselves, and the fact that the present appliances that have been introduced in the design of artificial treatment works are extraordinarily new, and might fairly be considered experimental, it is a reasonable conclusion that with the changes that have been going on in a short space of a little more than fifteen years, and most of it in the space of a little more than five years, possibly within ten years, there will be new lines in the treatment of sewage, and new processes that will revolutionize as completely the methods of today as

those methods were revolutionized only a very few years ago.

1523 The very first consideration in weighing various possible plans in any case would be the protection of the water supply. The absolute necessity of this exists where a water supply is in reasonable proximity to the works. That is in the discharge, for example, of the effluent of artificial works or of sewage for dilution within a certain range of distance subjects the water supply to pollution and to serious injury. At greater distances, further removed, of course, that becomes less important. In any case, the method should be such and the design of the works such as to absolutely prevent at any time the pollution of the water supply if that is within the range of possibility; that is even the contingency of pollution should be prevented.

It involves both the raw sewage and the effluent because there is no, absolutely no certainty that with the most modern works, most carefully devised and designed, that there will not be periods when raw sewage may be discharged.

And then, on the other hand, is the question of the efficiency of the works themselves in obtaining, if it is possible to obtain such a thing, an effluent that is entirely, at all times, free from dangerous pollution.

I give great weight to the danger which may result from the operation, that is, the inefficient operation of these plants, disposal plants, or the efficient operation of filter plants to filter water supply, owing to the absolute uncertainty of continuous, efficient operation in both cases.

The greatest difficulty is involved in the impracticability of handling the sewage otherwise than on a system of units, owing to the enormous volume of sewage, to the great areas covered, and the long period of time involved for the transit of the sewage to the treatment works. It involves the necessity of the construction of such works substantially within the city close to dwellings; that is in fairly close proximity to dwellings; and all experience on the treatment of sewage

today, so far as the location of treatment works is concerned, is in favor of their remote removal.

Baltimore, for example, one of the newest, and the larg-
1524 est city in America to put in treatment works, located the works something like seven or eight miles from the city, selecting a location remote from any dwellings. In addition to that, they felt compelled to buy large tracts of ground to create a neutral zone around their works, and yet, with a very short period of operation, and very low load on their works, only having part of the sewage to handle, they have been confronted with damage suits for the creation of a nuisance, by the owners of property along their holdings. The certainty in a very large community of the sewage reaching the works stale, its creating local nuisances along the line of travel in the interceptors, even with the entire area broken up into districts, is a great problem and a source of danger in a very large community.

The difficulty of handling the resulting materials accumulated, the sludge particularly, from the treatment works, its removal, its necessary storage in preparation for its removal, appears to me to be a most serious problem in considering any treatment works for very large communities.

In the years 1910, 1911 and 1912, the death rate from typhoid in Washington was 24, 22 and 22, respectively; per 100,000 population.

LYMAN E. COOLEY, witness for the defendant, whose qualifications have heretofore been stated (This narrative, p. 138; Rec. Vol. III, p. 1705), testified as follows:

The State Board of Health undertook to cooperate in the investigations that we were making at Chicago between 1885 and the passage of the Sanitary District Act in 1889, and
1706 made a very comprehensive series of analyses of samples through one summer and one winter, taken at various points between Lake Michigan and the City of St. Louis, in or-

der to determine the question of the self-purification of sewage introduced by the Illinois & Michigan Canal from the City of Chicago.

I made a study of the possibility of utilizing this great natural reservoir in passing waters by way of the Des Plaines and Illinois Rivers to the Mississippi River; and gave the matter general consideration at that time.

Later, I took up the matter as part of my duty as chief assistant to the Drainage and Water Supply Commission in 1886 and 1887. I followed the matter up, prepared a paper upon the subject matter in 1888, and brought the whole subject matter into final form in a series of papers before the Western Society of Engineers in 1888; printed early in 1889.

I later gave it further consideration, while a member of the International Waterways Commission. The instructions of Congress to that Commission were that we consider in full the water supply in connection with the development of ocean navigation into the lakes from the Atlantic Seaboard.

I have had occasion to make a study and examination of
1707 the necessities of the navigation interests and the improvement of navigation at Chicago and through the Illinois and Des Plaines Rivers.

That proposition was in view from the inception of the drainage enterprise, and in fact you might say from the time that the Chicago divide was discovered, in 1673; and it was a part of the policy of this State from the beginning to procure the construction of a waterway through the State. And when the Chicago sanitary question came up, and it was determined that the solution would require a large canal across the Chicago divide, the State, through its General Assembly, took the view that it should be constructed so as to lend itself to the development of a deep waterway through the State. And so from the beginning, the effect of this water which was needed for the sanitation of Chicago upon the regimen of the Illinois River and of the Mississippi River; and how it could be utilized in producing a waterway, was a prominent

factor and an important factor also in determining the policy of the State in granting the privilege to the City of Chicago of sewage disposal in the manner proposed.

I am familiar with the history of the State prior to the time when this matter was taken up. I acted as consulting engineer to a special joint committee of the General Assembly, which framed the Sanitary District law and was familiar with
1708 all the considerations that influenced that law, in Chicago and in the valley.

I was at Springfield during the entire consideration of the matter, and had general charge in the latter part of the session of the bill for the City of Chicago, for the City Council of Chicago and for the several civic organizations of Chicago, and I believe that I know as much about what the policy of the State was at that time, as anybody can know.

I drew some supplemental measures known as the Little Waterway Bill and the joint resolutions of 1889 and also of 1897, which were passed by the General Assembly, declaring the policy of the State.

I had at that time been over all the documentary evidence in relation to the subject matter, reports of various kinds, going back to that of Major Long in 1816; Phillips and Graham, in 1819, and to the report of General Gratiot, in 1834, in which the United States proposed at that time to construct a channel 10 feet deep and 100 feet wide; the land grant to the State of Illinois to aid in the construction of the Illinois and Michigan Canal; the report of the survey and examinations of John B. Preston, 1857 and '58.

John B. Preston, was a civil engineer in the State of Illinois, who made a project for steamboat navigation between Lake Michigan and the Mississippi River, in which the low water navigation of the Illinois River was to be made by aid of a water supply from Lake Michigan.

That proposition was followed up by joint resolution of the General Assembly in 1861, which called upon the canal trustees to examine the subject matter.

In 1862, there was a bill in Congress providing for such a waterway. The Honorable Thad Stevens made a speech, in which he denounced the proposition as a measure to drain Lake Michigan and convert it into a cornfield. So the objection on this lake diversion proposition goes back a long ways.

1866, General Wilson was charged with the duty of making a survey, and based his report of 1866 and '67 on the notes and data collected by John B. Preston in 1857-'58.

In 1867, General Wilson by the aid of a special appropriation from Congress made a survey of his own, which was
1709 reported upon in December of that year, and there was also a report on the Upper Illinois River by Colonel McComb, 1874 and by Major Benyaurd in 1883, and also upon the enlargement of the Illinois & Michigan Canal in connection with the Hennepin Canal in 1882-4, and by the Comstock Board in 1886 and '87.

All these documents gave a very complete idea of the physical conditions of the Illinois River and its possibilities of development, and were available prior to the passage of the Sanitary District Act.

Howard Stansbury, United States Engineer, made an examination of the Illinois River in 1838, and General Joe Johnson, later of Confederate fame, was upon the river engaged in improving the same in 1852 and '54. We had all that material.

I was the first chief engineer from January 1890 to December of that year; and a year later, December, 1891, I became a trustee of the Sanitary District and the chairman of its engineering committee until the close of my term in 1895.

1710 The Chicago River basin, as it originally existed in nature, consisted of the North Branch and its drainage basin, together with the South Branch, an area of about 240 square miles (now about 300 square miles). West of the Chicago River basin, was the Des Plaines River basin, drained by the

Des Plaines River which ran parallel to the lake from the headwaters in Wisconsin down to a point about ten miles from Lake Michigan at Lyons; and then leading southwesterly to a junction with the Illinois River, or to the junction with the Kankakee River, which formed the Illinois.

This Des Plaines River, in the vicinity of Lyons, had a low water elevation of about eight feet, and a drainage area of 633 square miles.

The divide between the Des Plaines River and the Chicago River was in the vicinity of the Bridewell, just west of Kedzie avenue, and had an original elevation of about 10½ feet above Lake Michigan, and whenever the Des Plaines River rose from two or three feet above low water, or exceeded a volume of about 1,000 second feet, the flow of the river divided, part of it coming through the South Branch of the Chicago River to Lake Michigan, and in great floods 60 to 70 per cent of the entire flow of the Des Plaines River came to Chicago.

This condition existed up to about 1854, after the Illinois and Michigan Canal had been opened in 1848, when the Drainage Commissioners cut out the original divide at Kedzie avenue and drained out the Mud Lake region as it was known in Voyageur's days, and on the original land maps as "Portage Lake, Portage Swamp, and Portage Slough."

For a number of years thereafter, the entire flow of the Des Plaines River came in the direction of Chicago except at such times as in the fall and winter when the ice interests of the Des Plaines River Valley made a temporary dam in order to fill the ponds on the 12-mile level between Summit and Lemont, for ice-making purposes.

Finally the flow from this source became such a nuisance to the City of Chicago that after 1870 they constructed the Ogden-Wentworth Dam. That crossed the old Portage Slough at the range line at Summit, at an elevation of something over 11 feet above Chicago datum. And this was overflowed also, whenever the river rose above a volume of about

1,000 feet per second; and the waters continued to come this way in flood times when the volume exceeded that amount until 1893, when the Sanitary District executed its river diversion and created a spill-way above Summit, which restricted the flow down the river until the volume reached between 3,000 and 4,000 feet per second. And in about 1909, 1711 this was finally closed, so that no waters from that source have come through the Chicago River to Lake Michigan since.

The effects of this overflow have been most pronounced and is noted from time to time in the narratives relating to Chicago and its portage. For a portion of each year boats in the fur trade made the trip from the Chicago River to the Des Plaines River and down the Illinois to the Mississippi River without any portage at all. For a portion of each year, a portage of two miles was required; for another portion seven miles, and in very dry seasons the portage was 51 miles to the junction of the Des Plaines and Kankakee Rivers at Dresden. Those conditions were availed of in trade and travel, from the time of the Discovery down to the time of the removal of the Indians from the State of Illinois in 1836.

The first white settler of Chicago, or the first white man to domicile here was Marquette, in 1674-5, and he was driven from his cabin on the West Fork of the South Branch near Robey street by a flood that came over the divide; and the next day he resumed his journey down the Des Plaines and Illinois Rivers without making a portage.

In 1832, the United States made an appropriation for opening the mouth of the Chicago River, and projected two piers from the vicinity of the present site of Rush street bridge, across the sand spit into the lake; and made a single dredge cut across the bar. This bar was washed out in 1834 by one of these floods that came across the divide.

A schooner entered the port of Chicago for the first time after this flood.

In 1849, a great flood came over the divide and cleaned out all the bridges in the Chicago River, wrecked all the shipping, producing a great disaster for its day.

The same thing was repeated in 1858.

In 1881, the water came over the divide for probably six weeks or eight weeks continuously, in large volumes.

In 1887, I measured a flow coming across the Chicago Divide of 7,000 feet per second, the flood of that year.

In 1892, this flood condition was very critically examined from the Chicago River to Lake Joliet, and a steamboat drawing three feet of water could at that time have gone from
1712 the Chicago River down to the Illinois River, and returned, in the absence of bridges. Aside from these conditions respecting the flood waters, the site of Chicago itself was substantially a morass, similar to what exists adjacent to the Calumet River up to a recent time, and still exists in some sections, awash in high waters of Lake Michigan, and overflowed in all these flood times. It was of much less extent than the Calumet marsh region; and along the lake shore there were the remnants of a sand spit, and wind blown sands rising from 10 to 20 feet above the lake; but generally behind that and out to the slopes beyond, the low lands bordering the Chicago River, the banks were only three to five feet high at low water, and consisted of ooze and muck and alluvial clay, interstratified with layers of sand.

The City of Chicago, or Village of Chicago was organized on August 10, 1833, 28 electors voting; population estimated at 350, from which I presume that none except those that were running for office voted.

At that time it was a mere frontier camp, and the usual well 6 to 12 feet deep in the front yard; slops thrown in the back yard; a privy vault on the back end of the lot. The soil conditions very soon made this intolerable, and the floods occurring annually diffused the deposits on these lots, without regard to sanitary discrimination.

As early as 1836, the conditions had so developed that the people were taking their water in pails from the 1713 river and from the Lake Shore; and the first water system of the City of Chicago consisted of barrels mounted on two wheel carts, that were backed down into the lake and peddled on routes, much like the milk routes today.

As early as 1836, a franchise was granted for a water company to supply the citizens with water, but owing to the panic of 1837 and the financial stress of that period, this company did not get its works installed until 1840; and these works consisted of a 250 barrel tank mounted on blocks at the foot of Lake street, with a 25 horse power engine, a short pipe intake into Lake Michigan and two miles of log pipe, bored out by hand; laid in the streets as a distribution system.

The people of even that day were adverse to monopolies, and did not patronize this water company to the extent of making it a financial success; still preferring the institution of a barrel on two wheels. So in 1851, a charter was granted to a water company, a new water company. The city had been organized in 1837 with a population of about 4,400 to 5,000 in 1840. In 1851, the population had reached about 35,000 and a new water company had been chartered; but the city finally took over the whole proposition in 1854 and established the works at the present site at Chicago avenue on the North Side.

There was some discussion at that time in regard to whether the site should be on the north side of the river or the south side of the river, but the general opinion prevailed that there was a lake current tending southerly along this shore, and it would be safer from pollution to put it on the North Side.

There was another event happening about this time, the opening of the Illinois and Michigan Canal in 1848. The first shovel had been thrown on this Canal at Bridgeport within the present city limits July 4, 1836; and that had contributed greatly to the growth of Chicago during its construction.

The first railroad out of Chicago was opened out to Elgin, also in 1848. The Michigan Southern Road came to Chicago in 1852.

There was a sickly period in Chicago between 1849 and 1854, in which the death rate rose to 48 to 50 in a thousand; three times what is now normal to well sanitated cities.

All these events, what was happening to the water supply, the death rate which had grown so enormously, the feeling that Chicago had ceased to become a mere camp and had
1714 a future before it, led the citizens to make an extraordinary effort to better the conditions here, in order that she might realize destiny. And so in 1855, or 1854, Mr. E. S. Chesbrough, of Boston, was employed as the Sanitary Engineer of the city; particularly at that time to devise a sewer system. Mr. Chesbrough went abroad and studied the conditions at Hamburg and at London and other foreign cities in 1856-7, but had submitted plans for his sewer system late in 1855.

In that connection I desire to say that this was the first comprehensive sewer system in the United States, and that we had at that time about 75,000 to 80,000 of population; and that other cities in the United States like New Orleans have only had a sewer system within the last ten years. Baltimore has not yet completed a sewer system.

I will say further that it was the second comprehensive sewer system built in the world. Hamburg had built a sewer system after its great fire, about 12 or 14 years before. London had started a sewer system, but its plans were not yet complete, and were not completed for three or four years later for a comprehensive system.

The state of the art up to that time had been that all human wastes were excluded from sewers by law. That was the law in England. And it was not until the report of the cities and towns commission in 1844 in England that that law was changed. At that time there had received general acceptance the filth theory of disease, and England and the Continent went on a general clean-up, you might say.

Berlin did not have a sewer system until 1860. All human wastes were excluded from the sewers of Paris up to 1880, so Chicago was a generation or so ahead of the world, and led the United States in regard to its sanitary provision in 1855.

Mr. Chesbrough planned his sewers so as to give a seven foot basement under the buildings, and as a result the grades of Chicago were established at 10 to 12 feet above city datum.

Street grades; and in many places the sewers were built on mounds entirely above the level of the ground, the natural ground, or on embankments; and walls were built on the curb line; and that is the reason for the general conditions that you notice in Chicago, that the basements all go out to the curb line so as to save the filling required to cover the sewers; and the sidewalk space beneath, which does not exist to the same extent in any other city.

1715 After the Great Fire, the grade was again re-established to the present level of 14 feet above the city datum. I was here in 1872, after the Great Fire in 1871, and remember distinctly the condition, that the sidewalk of the city was going up and down at every street crossing, on account of the new grades.

The sewer system then planned by Mr. Chesbrough discharged for the most part to the river. No sewers entered the lake on the north side, on account of the water supply. And the early main sewers came to the main river, so as to be within the influence of any circulation that might be established by way of the Illinois and Michigan Canal. The only sewers that were planned toward the lake was the one east of State street on 12th street and at 22nd street; and later when the city was extended down to 39th street, the 35th street sewer was added, also discharging into the lake. These plans were followed out substantially with the raising of the general grade of the city; and the conditions on the unimproved low lands continued as observed by me in 1872 and 1874 to 1878. Meantime the condition in the river itself was becoming intolerable.

On account of the great cost of raising the city to the grades required to produce a sewer system, the trunk sewers were laid on extremely low grades, 2½ to 4 feet per mile, which constituted them sewers of deposit in low water, under conditions of dry weather flow. And it was recognized from the beginning that catch basins and sewers would have to be cleansed from time to time, and it was only in storm time when the sewers were running substantially full that the sewers were self scouring, that is the trunk sewers.

The conditions in the river early became intolerable with the growing population. We had reached 125,000 by 1860. Chicago early became a packing center, and winter slaughtering was practiced at that time, before they had the refrigerator methods which permitted of all the year around slaughtering. And there had not been introduced at that time the saving in the by-products, bloods and other matter (this has since become a feature of Chicago slaughtering institutions), and everything went to the river, and so the river, particularly in winter time, became very bad.

Under some arrangement, the pumps were operated during the later fifties in the interest of a better river.

1716 The Illinois and Michigan Canal, as it was finally completed under the canal trustees, had a summit level of 8 feet above Lake Michigan, and it was fed in ordinary seasons from the Des Plaines River and by a feeder through the Sag Valley and the Calumet River at Blue Island.

That was known as the Shallow Cut Plan.

A dam was built across the Calumet River at an elevation of 11 feet above Chicago datum. This was insufficient in the dry seasons, and a Dutch Wheel or Lift Wheel was erected at Bridgeport, at the forks of the Chicago River and at the head of the canal for the purpose of supplementing the feed water of the canal, and in such seasons that was sufficient in cleansing the Chicago River and these were operated for that purpose in the later fifties.

But in 1863, after Chicago had established a Board of Public Works, the Chicago River became very offensive. An erysipelas epidemic occurred, which was co-terminus with the South Branch and was attributed to the blood and other matters from the slaughtering houses, and it was depicted on the spot maps as the "Valley of Death."

The Board of Public Works at that time made an arrangement with the Canal Trustees by which the Bridgeport Pumping Station should be operated and the city would contribute to the cost of doing so for the purpose of cleasing the Chicago River; and that arrangement continued up to the time that the canal deepening was completed in July, 1871.

Meantime the effluent from the river was contaminating the water supply, and Mr. Chesbrough projected the first lake tunnel in 1862. It was authorized in 1863. It was to be five feet in diameter, and extended out to the crib two miles from shore, and it was thought that this would give immunity for a long time in the future. It was believed that the effluent from the river for the most part would stay near the shore line, and would not reach out that distance into the lake.

Nevertheless, in designing that tunnel, he made his plans in such a manner as to invite an extension in the future without disturbing the existing conditions, providing an
1717 extension out from the crib in a separate shaft, so it could be shut off and extended at a future time.

This work was severely criticized by all the wise men of Chicago at that time, and Mr. Chesbrough's life was made a burden to him, but in 1867 it was opened, and attracted the attention of the world and made the reputation of Mr. Chesbrough as an international engineer. It has since been followed in all lake cities and followed in all water works practice, to the extent that tunnels can be made available.

He immediately followed this tunnel with a seven foot tunnel parallel to the five foot tunnel, leading from the same crib by way of the Chicago Avenue Station southwesterly across

the city some four miles from Chicago avenue to 22nd street and Ashland avenue. That station was opened in 1874.

The Chicago River at this time was in a deplorable condition. I was in Chicago nearly every day, or several times a week, from 1874 to 1878, and made a study of the conditions here, and was personally very well acquainted with Mr. Chesbrough. The North Branch, as I used to ride by it, between Evanston and the city, in the heated term of summer, exhaled an effluvia that compelled the passengers on the Northwestern Road to shut down the windows in order to keep themselves from being nauseated. No words can describe the potency of that smell.

This condition led Mr. Chesbrough to project the Fullerton Avenue Conduit, started in 1874 for the purpose of circulating the waters of the North Branch. It was put in operation in 1878, and as operated it changed the waters of the North Branch about once in three days, which greatly mitigated the badness of the smell. But it was still far from a satisfactory exhibit.

The South Fork conditions were even more serious than the North Branch; the smell from that source reaching out to the lake shore in the then best part of the city, down in the vicinity of the Douglas monument and above. This was noticed particularly in the night time and on foggy days. The sun seems to have some resolving powers in dissipating these smells.

Mr. Chesbrough projected a similar conduit to the South Fork, but his enterprise in behalf of the welfare of the city by that time had reached such a magnitude that he was unable to carry out that enterprise, and we retained the
1718 conditions of the South Fork with us until the Sanitary District finally changed the same along about 1908, I think.

Meantime, a Commission had proposed the deepening of the Illinois and Michigan Canal on the original plan; and in 1865 an enabling act was procured from the General Assembly

which authorized the City of Chicago to deepen this canal on the original plan for sanitary purposes; and the city of Chicago did so, and expended thereon about Three Millions in cash and opened the same in July, 1871.

That was gravity flow.

The General Assembly was called in special session after the Great Fire of October, 1871, and repaid this money to the city of Chicago, and it was all the funds that it had until the city was in shape to again realize taxation.

This canal as originally projected and worked on from 1836 to 1841, when the state went broke, had a declivity of a tenth of a foot per mile or 2.9 feet between Bridgeport and Lockport. But when work was resumed under the trustees for the bondholders in 1843, they adopted the expedient of a temporary level 8 feet above Chicago datum for 26½ miles, which I have already described.

The original divide at Kedzie avenue was about 10½ feet above Chicago datum called the "Continental Divide."

But this was a mere alluvial deposit. The real divide was the rock floor at Lemont which was between 7and 8 feet above Chicago datum, and about 2 or 3 feet above the high water of 1838, which was the highest water on record. The original divide was only 5 to 6 feet above high water of 1838.

This was the only relief that the city had until the canal was reinforced by pumping works in 1883. The canal when opened to gravity is estimated to have carried out 40,000 cubic feet of water per minute. But the lake was then high, and in later years as the lake fell, the capacity shrunk to 15,000 or 20,000 feet per minute, which was scarcely more than the dry weather flow and the water supply of the city, so it was ineffective in preventing the sewage from flowing towards the lake. And the condition of the canal became so bad that at the instance of the State Board of Health, first in 1878, when it was organized, I think, in 1877, the Munn 1719 Resolution was passed by the Legislature in 1881, calling upon the City of Chicago to erect pumping works there of a capacity of not less than 60,000 feet per minute.

These pumping works were installed in 1883, but were not actually accepted from the contractors and taken over by the city until 1886, although they were operated meantime.

These pumping works were authorized by the Legislature in response to the representations of the State Board of Health, which had taken a position supported by the report of Superintendent Thomas that the canal could be made to carry 100,000 cubic feet of water per minute, and that such a volume of water would dilute the sewage substantially beyond offense. But they did not get the recommendations carried out except with the minimum limit of 60,000 cubic feet. It was for the purpose of relieving the nuisance at Joliet, and in the Valley further down; and also for the purpose of purifying the Chicago River that these pumps were installed, or called for by the Legislature.

Mr. Chesbrough was uncertain in his own mind in 1878 as to what the future solution of the sanitary question was to be. He had planned along the line of the State Policy, which had contemplated from the beginning the flow of water in the direction of the Illinois Valley, and which comes up from time to time in all the actions of the state. But the city was unable to finance a proposition of that kind. Conventions had been had, reports had been made; there was a
1720 Great Waterway Convention in 1847 and again one in 1863, in which 14 states were represented, urging this project; the Board of Public Works had considered it in 1860, so the matter was a familiar one to the people of Chicago, the idea that eventually sewage disposal was to be down the Des Plaines and Illinois Valley.

The only incident that occurred of particular moment between 1878 and 1885, was the Great Flood in the Des Plaines River. This flood reached a magnitude of 13,000 second feet; continued at a uniform elevation for about four days; gradually shrunk, but exceeded 10,000 feet per second for 21 days, at Riverside. There was probably from 5,000 to 8,000 cubic feet per second coming across the Chicago Divide during that time; and a lesser amount probably for two or three times as

long a period. In addition there was probably a maximum flood from the Chicago basin of not less than seven to 8,000 feet. These conditions swept the Chicago River clean and led the people of Chicago to renewed earnestness in the consideration of their sanitary problems. Between that time and 1885 various projects were mooted, one of which was to shift the water supply to Grosse Point, the north limits of the City of Evanston; another to shift it to Highland Park in Lake County, and let the water come down by gravity. Another was a deep cut proposition which was worked up by Mr. Matthiesen at Joliet, by which a narrow and deep channel with high velocity was to be constructed from the Chicago River and located between the Illinois and Michigan Canal to the Des Plaines River; and discharging in the upper basin at Joliet.

The Citizens' Association of Chicago had taken particular charge of this matter and had worked up this latter proposition of Mr. Matthiesen's and made a report thereon.

1721 On August 2, 1885, occurred a rainfall of over 6 inches in 24 hours, the greatest precipitation that has occurred during Chicago rainfall record, beginning in 1843. The effect of this rainfall was to sweep out the contents of the Chicago River; to scour out all the sewers and catch basins and to wash the streets. The entire effluent went into the lake and filled the lake with a black filthy mass extending several miles north and south along the shore, and out beyond the crib. And its effect was visible in the water supply for a long time afterwards.

The Standing Committee of the Citizens' Association appointed a sub-committee consisting of Mr. Ossian Guthrie, who had operated the Bridgeport Pumping Station, since its installation in 1848 up to the time it was abandoned in 1871 by the deepening of the canal. He had ice interests in the Des Plaines River, and was thoroughly familiar with all the flood conditions at Chicago. They selected also Doctor Frank Reiley, who was then the Assistant Secretary of the State Board of Health of Illinois, and they selected me as engineer.

We made a general examination of the situation, visited the Des Plaines River and all the points of interest in connection with the phenomena, and wrote a report which I drew; and this report substantially unchanged was adopted by the General Committee of the Citizens' Association, and printed in all the Chicago papers on August 27, 1885. A rainfall not quite so large occurring a week or two later, also producing a large flood, came in to re-enforce the findings of the report and give them general credence and acceptance among the people.

This report contemplated or recommended that all storm waters including all sewage be permannently excluded from Lake Michigan; that a channel large enough to accomplish this be built through the Des Plaines Valley to an outlet near Joliet; and that in order that this channel should not be unnecessarily large, the headwaters of the Des Plaines and North Branch should be diverted to Lake Michigan. Of course it involved taking out all the sewers and reversing them, or intercepting those that emptied into the lake; and also providing a circulation in those parts of the river which had no circulation; parts of the harbor.

This proposition was followed by an ordinance of the Council which I drew, and which was promptly vetoed by Carter Harrison, Senior, on the ground that the city had no means of financing the undertaking; and it was vicious to discuss these propositions, and unpatriotic under those circum-
1722 stances.

Later Mr. Harvey B. Hurd, went to Mr. Harrison and pointed out to him a constitutional method of raising money through the creation of a blanket corporation, such as we have precedent for in the Park Boards, with its own power of taxation and bonding. Mr. Harrison later sent a message to the Council recommending the appointment of an expert Commission, and this was adopted.

In April, 1886, Mr. Rudolph Hering of Philadelphia was selected as Chairman of the Commission, and later Mr. Samuel

B. Artingstall, who had been assistant engineer to Mr. Chesbrough and was then city engineer, was made a member; and also Mr. Benezette Williams, who had been an assistant engineer to Mr. Chesbrough, and who had recently completed the Disposal Works at Pullman, which were looked upon as model works at that time, and an augury of the future disposal of sewage, by scientific and rational methods. I became chief assistant in general charge, in the absence of Mr. Hering, of all the work, and in special charge of those parts of the investigation which we are particuary concerned with in this inquiry.

I had the subject of streams examination through all the water sheds that affected the Chicago condition, the lake currents, lake levels, the ship canal surveys, borings, calculations of the capacity of channel; the Illinois River problems; its effect on the Illinois River of the proposed flow of water from Lake Michigan; the examination of the Chicago River and its contents and of the special filth producing industries; an examination of the conditions of the Illinois and Michigan Canal; an examination of the conditions produced in the Illinois River by the sewage which had been sent down the canal. Mr. Swan of Boston had particular charge of the investigations relating to land disposal, sewage treatment and lake disposal. Mr. Swan was a man who had been connected with the Massachusetts Board of Health, which had made perhaps the most extensive researches up to that time respecting the pollution of streams; and he had also made a number of trips abroad.

1723 I had included in the report of the Sub-Committee to the Drainage Committee of the Citizens' Association a statistical statement to show that Chicago would reach one million inhabitants in the year 1890, and would be able to finance the undertaking. I was asked to strike out that matter as it would discredit the report, as nobody in Chicago believed that this city would reach a million inhabitants in the year 1890. There was no member of the committee who believed it; and so I struck it out, as it had no material bearing upon

the project itself. There were on that Committee such citizens still living as J. J. Glessner and J. Harley Bradley.

1724 I also made a critical examination of the Chicago River and its contents, and dredged up every acre of its bottom within the city to ascertain the nature of the deposits there occasioned by sewage. The Chicago Harbor has an area of about 450 acres, which was actually used for shipping purposes. This river, as I have already stated, was swept clean in August, 1885.

In the Fall of 1886, it had a sludge deposit in the North Branch from a foot and a half to 6 feet in depth; and in the South Branch about 4 feet in depth. This sludge was not what is ordinarily termed sludge in the nomenclature of sewage disposal. It was a black, jelly-like mass full of cavities like Swiss cheese, indicating a secondary decomposition, and emitting gases on its own account; and from all the studies and examinations and knowledge which I could acquire in regard to the same, it appeared to be largely hydro carbon, bacterial gases that are thrown down through the decomposition. I estimated that the South Fork would have filled up in four years from these deposits, except for the progressive decomposition that was going on.

I repeated this examination after the spring flood of 1887, and found that the river had been swept clean of these deposits.

1725 Those went out into the lake.

They were of that constitution, so cellular in composition that when they are once broken up by a propeller or other disturbing forces, they would float readily in the water.

I also made an examination of the Illinois and Michigan Canal to ascertain its condition respecting these sludge deposits and what current must be maintained to keep the same from settling on the bottom. I found practically no deposits similar to those which I have described in the Illinois and Michigan Canal. There were deposits in wide water, which consisted very largely of earthy matters; and it seemed

to be that a velocity of ½ to ¾ of a mile would maintain all these substances in suspension.

I also made an examination of the conditions in the Illinois Valley since the sewage had been down there through the canal, and made an extended trip from Joliet to La Salle, interviewing all the people and fishermen who were familiar with the condition of the river, respecting that subject.

We had a breakup flood in 1887, occurring the latter part of February, which reached 10,000 second feet at Riverside, but was of extremely short duration, as a freezeup set in the next day, after the flood got fairly under way. I measured that flood in the North Branch and in the West Fork of the Chicago River, where I ascertained that 7,000 second feet was coming across the divide. I also had a party at Riverside. Mr. Hering was in personal charge of a party at the mouth of the Chicago River, and as I recall measured 12,000 feet of water going out into the lake in that flood, which was by no means an extraordinary flood.

A preliminary report of the Commission was made January 30, 1887, and in that report they considered three methods of sewage disposal for Chicago.

One of these methods was to gather up the sewage by intercepting sewers and conduits, and pump the same to the sand ridges and dunes of Indiana, east of Hammond, and between the Little Calumet River and Lake Michigan; and there dispose of the sewage on land by broad irrigation and intermittent filteration. This scheme was regarded as impracticable by reason of divers political jurisdiction, and by reason of cost. And it still left problems to be solved in the circulation of rivers and the care of floods. It was known even at that time, and more fully developed later, that the condi-

tions of flood waters and especially the conditions of the
1726 water in the Chicago River when this city was taking a

bath, the sewers were being scoured out and the streets washed, were worse than at any other time. And no such scheme could care for these food conditions; and the condi-

tions for the maintenance of proper sanitary conditions in the river itself.

The second scheme worked out was like the first, so far as gathering up the sewage was concerned, and a conduit was to be driven out into the lake opposite Jackson Park and the sewage there forced out through this conduit and diffused in the lake. The water supply was to be shifted north to Grosse Point at the northern city limits of Evanston. This proposition was estimated, and it was also regarded as prohibitive. It was strongly objected to on the score of possible contamination of the water supply even at that distance, as the lake currents showed that to be possible: and also for sentimental and other reasons. The effect would be to pollute the bottom of the lake here over a very large area to be stirred up in storms and result in a bad condition of the water in this end of Lake Michigan. It also failed, like the first scheme, to take care of flood water conditions, and the circulation of the river.

The third proposition, which was affirmatively recommended, was the ship canal solution, substantially as outlined by the report of the Citizens' Association of August, 1885, and the capacity of the channel which it was then determined it would be necessary to take care of the flood conditions was fixed at not less than 10,000 second feet.

This would also take care of the Chicago River and produce proper circulation in its branches by means of adjuncts. The population estimated in all these schemes was two million and a half people, and on that basis the dilution was inferred at four cubic feet per second for each thousand of population; although this matter as to what population such dilution would take care of or such volume of water would take care of was not specifically passed on at that time.

It had other collateral merits which were mentioned. It would lend itself to the development of an inner harbor here in Chicago and would provide the water supply required to produce a deep waterway to the Gulf and would contribute to the extent of the cost of the main channel of such deep wa-

terway, without expense to the State or to the United States, all of which were motives which left no doubt as to the proper scheme to select.

1727 Following this report, a bill was introduced in the General Assembly known as the Hurd Bill, the same being drawn by Harvey B. Hurd, an eminent constitutional lawyer of Chicago, which provided not only for the construction of this work, but also for taking over the sewer system and eventually the water system of the city, so as to combine under one jurisdiction all elements of the sanitary problem in Chicago.

Extensive hearings were had, which were printed at the time, before a Joint Committee of the General Assembly, which went into the merits of the whole question as then understood. The General Assembly considered the subject matter unripe for action and postponed the Hurd Bill, and passed a subordinate bill known as the Roach-Winston Bill, which gave authority to divert the head waters of the Des Plaines River and North Branch to Lake Michigan and enter upon other expedients of temporary relief pending the development of the major project.

The General Assembly also authorized a Joint Committee to sit *ad interim* to investigate the whole subject matter and report back to the next General Assembly; and constituted the Mayor of Chicago *ex officio* chairman of this committee.

The Drainage and Water Supply Commission reported on the schemes covered by the Roach-Winston Bill, in July, 1887, and did project various measures of temporary relief such as extending the water tunnels, enlarging the canal out to Summit, or the Ogden Ditch, and putting in pumping works there to pump 120,000 cubic feet of water per minute, but none of these measures were actually carried out.

The investigation of the Drainage and Water Supply Commission continued after this report until November, 1887, and then the Commission was disbanded, without ever having made a final report or completed all the topics which it had

undertaken to consider. Following the disbandment of the Commission, I entered into the service of the State Board of Health of Illinois, as its consulting engineer.

The State Board of Health, in cooperation with the City of Chicago, had in 1885 and again in 1886, made an extended series of chemical analyses of samples from a number of points between Chicago and Peoria for the purpose of determining the effect of sewage in the Illinois River and the purification of the same. They presented a very sanguine report in 1886, in regard to the progressive oxidation of the sewage downstream, which was challenged and much criticized by the sanitary world as a misinterpretation of the facts; that the real cause of the purification shown was sedimentation and dilution, and not purification.

1728 The sanitary world at that time had been much impressed and still entertained the dogma which had been pronounced by the Royal Rivers Pollution Commission of Great Britain, which had issued a dictum much quoted even to this day, that there was not a river in Great Britain long enough to purify itself.

My work with the State Board of Health consisted of various examinations and consultations here at Chicago, special examination of the Illinois River, in which I twice examined the conditions produced by the distilleries and the cattle pens of the Corn Products factories at Peoria and Pekin, which were producing a condition in the Illinois River at that time for 20 to 25 miles below Peoria only less offensive than that which existed in the Chicago River.

In 1888, they undertook a very comprehensive series of stream examination of the Illinois River and its tributaries, and the entire route from Lake Michigan to St. Louis, and continued these observations into the winter months of 1889. And I undertook to work up the physical facts connected with the flow of the river in that connection. These results were published in a preliminary report in 1889, along with my own contribution respecting the Illinois River System, and were before the Legislature in the session of 1889.

In the spring of 1888, the special joint committee of which Mayor Roach of Chicago was Chairman, got busy and employed Mr. John P. Wilson as legal adviser and he called in consultation eight of the most eminent constitutional lawyers that were then in Chicago and the State, to determine the legal basis of a proposed Sanitary District Act. I was employed as consulting engineer to this committee; and in the subsequent months hearings were had in Chicago and in the Illinois Valley in relation to all matters in controversy.

I was called upon particularly to pass upon and determine the capacity of the channel, and adopted the prior determinations that it should have a capacity of not less than 600,000 cubic feet of water per minute, but that in order that Chicago would be better able to finance it, only the rock cuts were required to have this capacity at the outset; the earth cuts permitting progressive development with the growth of population; and it was so entered in the law, or in the bill then prepared.

The other question that I was called upon most particularly to consider was the subject of proper ratio of dilution.
1729 There was a difference of opinion in the Commission itself and in the hearings, ranging from 14,000 cubic feet of water per minute for each 100,000 of population up to 30,000 cubic feet of water per minute, and the subject matter was finally referred to the consulting engineer to make an exhaustive investigation as possible, and that whatever findings he made in the premises would be satisfactory to all parties.

At that time we had not only our own investigations here in Chicago and in the Illinois Valley, which perhaps were more comprehensive than had ever been undertaken upon a similar subject and upon a much larger scale.

And we had also the very excellent reports of the Massachusetts Board of Health, and some from other New England States going back for 15 years or more, dealing particularly with the subject of river pollution. We had also all the reports that had been made by Royal Commissions in Great

Britain; the reports in regard to Paris and Berlin, and other foreign data.

In addition to this, I made a special compilation of the population of American cities in relation to the low water supplies of streams into which they discharged their sewage. So I felt then, and feel now, that we had all the data which was available for such a consideration. We had on the one hand a city so situated and conditioned that all the sewage that was produced by its population was practically tributary to the sewer system, perhaps more completely so than in any other city of the world . We had also at that time the established leadership in the preparation of food products of vegetable and animal origin, and the waste from those sources in themselves amounted to the equivalent of a very large city. But in respect to this matter, it was reasoned that there had been a very great development in by-products from these industries in the past, and that probably by the time the capacity of the channel approached exhaustion these wastes would be all converted into useful commercial products, so that there would remain substantially only the domestic sewage in the eventual windup.

On the other hand most of the data existing here and abroad were cases of actual pollution of streams, of natural streams which were all highly charged, in some cases to their practical limit in digesting the organic remains from the land. That matter had come up for very careful and full consideration in the studies by the State Board of Health, or under the direction of the State Board of Health, and we had made estimates of the organic product from the Illinois water-
1730 shed, a very rich watershed, in its vegetal cover which showed that the organic wastes coming to the stream from this source were manifold.

These facts had led to very high estimates in different localities and in different countries in regard to the ratio of dilution that was tolerable in streams; whereas we had at Chicago a lake water charged to its limit with oxygen, in fact surcharged much of the time, so that it was not a case of

river pollution in fact, but a case of contributing a new stream to the Illinois carrying its own standard of purity.

After going over all these matters which I have outlined, I determined the ratio at 20,000 cubic feet of water per minute for each 100,000 inhabitants, as a minimum. The bill as drawn was submitted by the committee to the General Assembly as its report, February 1, 1889, and was passed in May of that year without any amendments whatever as affecting the sanitary provisions of the bill.

I was instructed to remain in Springfield by the Mayor of Chicago, and was eventually left in charge of the measure after the preliminary hearing. I am able to say that every feature of the bill that affected the Illinois Valley was canvassed at great length. In my work for the commission, I had the assistance of a party of men, among others Mr. John Erickson, now City Engineer of Chicago; and we were called upon and did compile everything relating to conditions in the Illinois Valley, and made the best estimates that it was possible to make at that time regarding the effect of this volume of water in the Illinois Valley. And those matters were fully explained.

In order to further safeguard the interests of the Valley, provisions were put into the bill to remove certain dams belonging to the State. A supplemental bill was drawn. I myself drew it at the request of the Valley interests providing for a cession of these dams to the United States, on condition that they should remove the same and change its policy to a deep water policy in conjunction with the water supply from Lake Michigan. In the event of the United States not accepting the same, the canal commissioners were directed to remove the dams whenever the water turned down from Chicago should give an equivalent depth for navigation.

1731 A joint resolution was passed by the General Assembly, which I prepared by request stating the policy of the State, which was to produce a channel not less than 22 feet deep across the Chicago Divide to Lake Joliet, and not less than 14 feet deep thence to Utica, so fashioned as to permit fa-

ture increase in depth, and requesting the United States to stop work on the dams at La Grange and Kampsville and enter upon a policy of deepening the Illinois River by dredging, in conjunction with this water supply from Lake Michigan, and produce such depth as might be feasible by such method. This resolution was repeated in 1897, which I also drew by request, and there the proposition is mentioned of 14 feet through the Valley, which is the origin I think of that phrase.

Our examination of the Illinois Valley had determined that 14 feet could be produced by the aid of this water supply; and that by producing such depth of water, this channel would be self-sustaining and not subject to depreciation and would make a better drain for the Valley, and assist in the reclamation of the lands. All these matters were prime factors, as well as another matter which was uppermost in the minds of the State Board of Health and in the minds of the General Assembly, and that was that the solution that served Chicago would likewise serve all the populations that could exist between Chicago and the Mississippi River, by reason of the progressive purification of the sewage, through which it could take on an additional burden from point to point.

After the passage of this bill, the subject matter of a petition for the organization of the Sanitary District was taken up by the Citizens' Association, and I acted as consulting engineer to the petitioners and prepared a number of exhibits which were submitted to a committee of Judges of the Circuit Court, which was provided for by law, who held hearings and entertained objections in respect to the proposed boundaries of the District, and to finally determine the same. These hearings were continued over a number of days, and all interests subject to taxation within and without the proposed district appeared. And it became necessary to develop before this Commission a complete project, to determine you might say a complete project by which the Commission could judge that every part of the territory which it was proposed to tax would be benefited and could be served.

They finally determined the boundaries of the district on the North by the north line of Lake View and Jefferson; on the West, the west line of Cicero, and along the range line through the township of Lyons, including outside thereof some eight square miles along the Des Plaines River below Riverside; thence easterly along the south line of the
1732 Town of Lake and across Hyde Park at 87th street; the same including 185 square miles.

At the time of the passage of the Sanitary District Act, this area was divided up into a number of municipalities. The city of Chicago itself covered 37 square miles and had a population in 1888 of 802,651; the town of Lake View 42,339; Jefferson, 10,622; town of Lake 56,661; Hyde Park north of 87th street 41,000.

All these areas above scheduled were consolidated with the City of Chicago at the general election in 1889 by authority of an act of the General Assembly. There was in addition the town of Cicero, with a population of 13,926 and a part of the township of Lyons with a population of 1,293, and these together aggregated nearly 1,000,000 (988,329). The proposition was voted upon at the general election in November, and the Sanitary District Act was adopted by vote of 70,000 to 200, in round numbers.

In the December immediately following, a special election was held for trustees; and the Board finally organized as a Board of Trustees of the Sanitary District in January, 1890, and elected its officers. I was elected Chief Engineer for the Sanitary District, and entered upon my duties at once. These consisted in bringing together all the data and exhibits that had been prepared during the prior investigations until the Supreme Court decision affirming the validity of the act was handed down on June 12, 1890.

Immediately thereafter an engineering force was organized on a large scale and proceeded with the definitive surveys which preceded construction, and the actual carrying out of the work itself.

At that time, our particular studies and surveys were directed towards locating the main channel and the river diversion from the Chicago River to Joliet, and making all land surveys required in connection with acquiring the right of way; and of course with a view to putting that work under construction as soon as possible.

Later, and in the course of my first term as engineer and trustee of the Sanitary District we completed compre-
1733 hensive surveys extending over the entire area of the District and outside of the same for the purpose of taking up the border definitions on the collateral projects.

The plans except as to details and except as to specific definition had all been practically determined before the law was passed, and were exhibited with all needful detail before the Committee that determined the boundary of the District.

The plans of that period not only exhibited an auxiliary channel from the main channel to connect with the little Calumet River, but also the Evanston Channel. In fact the Calumet proposition was worked up by the preliminary report of the Hering Commission in 1887 and was always regarded as one of the integral parts of the comprehensive plan.

It was further developed or reported upon in 1896-7 by the Intercepting Sewer Commission of the City of Chicago; and also considered at length by the Committee on a comprehensive plan in 1901. I was a member of the Intercepting Sewer Commission and also the Committee on Comprehensive Plan.

Plans with reference to intercepting sewers for the city of Chicago were considered from the beginning, and plans were actually made in connection with the disposal schemes in Indiana and in the lake for intercepting the lake shore sewage, and this matter was taken up in final preparation for work by the Intercepting Sewer Commission or what was known as the Pure Water Commission of the City of Chicago in 1896, and definite plans prepared which have since been car-

ried out with some amendments covering the entire city front from 87th street on the south to the northern city limits. There were two of the sewers that discharged into the lake under the old Chesbrough plan, the one at 12th street and the one at 22nd street, and they were actually reversed on or about this time.

The Sanitary District was instituted for the specific purpose of carrying out the projects which were outlined prior to its organization, and had proceeded by September, 1890, in the definitive surveys in relation to the main channel from the Chicago River to Joliet. They had also instituted sur-
1734 veys on the Chicago River with a view to the definitive surveys for its enlargement.

When I became chief engineer in January, 1890, I proceeded immediately to further work upon those plans for the Sanitary District.

There was nothing left to do except to define the things on the ground, practically. The genius of the whole proposition from the outset, held in mind unvaryingly, was to keep the flow of sewage away from Lake Michigan as far around the rim of the lake as was practicable.

After December, 1890, when I ceased to be the chief engineer I again resumed my connection with the State Board of Health as consulting engineer, with a view of completing the report which had been made in preliminary form in 1889, and putting the whole subject matter of our knowledge of the conditions in the Illinois Valley in proper form for printing and record.

1735 No water supply has ever been entertained for the City of Chicago except Lake Michigan. and no other source of water for the city is really feasible, except Lake Michigan. The water supply from all the Great Lakes has been regarded perhaps as superior to any source of water supply elsewhere existing in this country, by reason of the age of its waters, through which all the biologic processes of nature have worked

themselves out, those that are in any way detrimental to human kind.

The average flow over Niagara Falls would take one hundred and fifty years to drain out the contents of these lakes, if they were not replenished and in the absence of evaporation. The Chicago Sanitary Canal, if operated at 15,000 second feet, would be supplied for 2,000 years, so the average age of the water of the lakes is 150 years.

There is no possible substitution for these waters, which could equal them in value or efficiency. There is no possible treatment of water which is the equivalent of these aged waters. The matter of age in waters has been given in
1736 the last few years a very great deal of consideration.

Mr. Frederic P. Stearns of Boston in the Metropolitan Boston Supply projected a reservoir there and places considerable stress by reason of the fact that the average age of those waters will be six to eight years, and they will have time to whiten and bleach, and work out their biologic cycle.

The same proposition I had up in connection with the Denver water supply where I was instrumental in constructing a reservoir that would carry three years' supply for the City of Denver, and secure the same object.

There is very little land water going into the south end of Lake Michigan; the nearest point of any tributary of considerable size being the mouth of the St. Joe River, more than 60 miles away.

The sanitary project contemplates and has contemplated from the outset extending this divorce between land waters and lake waters as far around the rim of the lake as possible; north to Lake Bluff at least, on the north and east across Lake County in the State of Indiana; and when the proposition is entirely worked out there will be some 60 and 70 miles of the lake shore entirely free from the intrusion of any land water or sewage whatever. And this puts Chicago in a better position in relation to its water supply, and secures for it a better water supply than is provided for perhaps

in any city in the world; one that is automatically free from contamination or possibility of contamination.

After 1883, the Illinois and Michigan Canal was operated up to a limit of 60,000 feet of water per minute or a thousand feet per second, which was little in excess of the ordinary flow of the sewers coming from the water supply and the ground waters; and the result was that any rain of any considerable amount that produced any run-off at all in the sewers or in the watersheds outside of the sewerage area
1737 produced a flow towards Lake Michigan, which entered the lake water and contaminated the same.

There were also conditions where lake fluctuations produced a similar result. This bobbing of the lake up and down, which I have observed through a range of eighteen inches every twenty minutes, had the effect of sending the current up the river, and then set it back again, amounted to a species of milking process, by which the content of the Chicago River was gradually milked out into the lake.

Again, there were other changes; sometimes the lake would be up an extra foot, and all the bad waters would be sent up the slips and the South Fork and North Branch, and fish would attempt to make a trip through the blue waters of the river and the lake would fall as quickly, and all the bad waters would set out into the channel, and we would have large numbers of dead fish in the river and in the canal.

The South Fork was without circulation during this period, and in a malignant condition.

The North Branch had only the nominal circulation created by the Fullerton avenue conduit, which was changed once in about three days and was in a bad condition. Of course in flood time, when there was any considerable amount of water, the contents of the river went out in a most affirmative way into the lake.

I will say, further, that the duration of this positive flow into the lake was variable. Under the conditions of the flood of 1881, it probably was not less than 100 to 120 days; prob-

ably in the minimum years not less than twenty-five or thirty days, but that is an estimate and not a positive determination.

The smells were affirmative in the North Branch along the main river, and beyond any power to describe the same in the South Fork. In the examination which I made in 1887—1886 rather, I was on the river in a tug for several days dredging every acre of its content to ascertain the character of the deposits on the bottom. These were brought up and spread over a broad table on the fantail of the boat and examined carefully by working them over with a paddle and examining them with a glass, and samples of them taken from time to time for more critical examination. And in my trips up the river, and especially up the South Fork, men were
1738 so nauseated that they were unable to take their meals, and some of them did not recover for a week.

At times there would be a scum, sometimes extending clear across the South Fork, which appeared to be six or eight inches thick, and over which the fowls, geese and duck of that region, proceeded without difficulty. I have heard of that scum having been afire; and the vessels that went up into those forks lost their white paint very quickly.

There was noticed, however, in the death charts which I prepared in regard to zymotic diseases in Chicago, covering the years 1890, 1891 and 1892, that the deaths from miasmatic or air-breathing diseases seemed to be more prevalent in the region where these bad gases were most intense. And in the inquiries which I made at that time among physicians, it was generally recognized that throat troubles and other air-breathing maladies were more malignant where these emanations were breathed.

This pollution of the Lake Michigan water had an effect upon the death rate from typhoid fever and other water-borne diseases.

I investigated a typhoid fever epidemic in Lake View in 1889 for the State Board of Health, and later followed the

matter up in 1891. The epidemic that started in Lake View continued with ups and downs through 1890, 1891 and 1892, and then gradually subsided.

In 1891, the death rate in Chicago was 480, I believe, in May of that year, and for the entire year the number of deaths from typhoid as then diagnosed was something over 1,700.

Estimating the population at 1,000,000 within the city proper, it would be 170 per 100,000.

1739 I sent men to the health records, or to the records at the City Hall and we went through the entire list of deaths of the year. At that time they were not classifying and printing a classified statement of deaths. We made a card for each name for each location, and then proceeded to spot it out on the map. In that way we made up the charts for the years 1890, 1891 and 1892, for the particular purpose of disclosing that epidemic, and also the relation of other zymotics.

I was elected as trustee, and took office as a trustee in December, 1891, and continued in that position until December, 1895, and during that period we executed the Des Plaines River diversion, a collateral work of the main channel, by which the river was given a course by itself on the west side of the Des Plaines Valley, so as to leave an intermediate strip between the river and the canal, on which we located and built the Drainage Canal.

At the end of 1895, excavation on the Main Channel was about three-fourths actually made or completed. The right of way had all been procured at that time; the contracts for the Main Channel were also arranged before the close of my term as to be completed in November, 1897.

I was consulting engineer of the District in 1897, and we were overtaken at that time with a financial stringency, which seriously embarrassed the progress of the work of the District. The work was proceeding faster than the District could get the funds to pay for it, and so the real work on the channel, the Main Channel, which was scheduled to be completed

in November, 1897, was not actually completed until about November, 1898, when it was substantially completed, and the District then notified the Governor of that fact and asked for the appointment of a commission. The first action by the Board on that matter was in November, 1898, and the petition actually was transmitted to the Governor in January, 1899, as I recall it.

1740 There was a delay at that time in view of the fact that the state had made no appropriation for the maintenance of this Commission, and the Sanitary District deposited the necessary funds with the State Treasurer, and the Commission proceeded later to perform its functions, and the Sanitary Canal was finally opened on the recommendation of the Commission to the Governor, January 17, 1900.

The channel was then opened and the water flowed through the Main Channel into the Des Plaines River, and has been flowing continuously ever since.

Very elaborate surveys were made of the Chicago River for the purpose of defining the property questions at the place of the enlargement while I was a trustee of the District prior to 1895; and the work of actual enlargement of the river began in 1896.

The United States took jurisdiction of the Chicago River and exercised authority over it for the first time under the clause in the Rivers and Harbors Bill of 1896, and a permit was then issued to the Sanitary District for the improvement of the stream, by the Secretary of War. The stream was prepared for a flow of 300,000 feet of water, the preliminary requirement of the Sanitary District law, some time prior to the opening of the channel.

After the flow of water had been established, in 1900, the Sanitary District then matured plans for enlarging the river for the purpose of getting the larger quantity of water required by the Sanitary District Act, and actually entered upon that proposition in 1900; and the whole subject matter was before the Commission on a comprehensive plan of 1901, of

which I was a member, and the trustees went to the Legislature and got an enlargement of their bonding power for the purpose of expediting the work in 1901.

The improvement made prior to the opening of the channel was simply preliminary improvement. It was recognized that in order to obtain this flow in the quickest possible time
1741 and at the lowest possible expense, it was recognized that there would have to be a wholesale improvement from the beginning, such as was undertaken in 1900.

I refer to a resolution passed by the Board of Trustees of the Sanitary District of Chicago on April 21, 1891, appearing in the printed proceedings of the Board as follows:

> "Resolved, That this Board hereby ordains that the Sanitary District of Chicago do forthwith enter upon, use, widen, deepen and improve the Chicago River from its mouth at Lake Michigan to the South Branch thereof, and also the South Branch thereof, together with the South and West Forks thereof, so as to make the same a proper and sufficient supply channel for the Main Channel heretofore surveyed from the Chicago River to Joliet;
>
> And further, that the acting Chief Engineer be and he is hereby directed immediately to investigate and report upon the capacity of said river and its said South Branch and Forks for that purpose; and also as to any changes that should be made therein. And that a copy of this resolution, certified by the Clerk, be forthwith transmitted to the Mayor and Common Council of the City of Chicago and the Secretary of War of the United States."

The Chief Engineer of the District went ahead and made an exhaustive survey of the Chicago River from Robey street to the lake, defining all property rights and cross sections of the stream, with a view to definitive plans for the improvement of the river. And these surveys were completed prior to 1895. They were followed by definite plans for the improvement of the river, which were inaugurated in 1896, in cooperation with the United States, which made an appropriation for the improvement of the river in that year; and the river was improved to a depth of twenty feet by dredging the stream. And the bad angles in the stream were cut off,

and in some places the river was widened, and in the vicinity of Adams street and Jackson street, by-passes were con-
1742 structed at the constricted parts of the river, in that vicinity, for the purpose of giving the preliminary flow required by the Sanitary District law of 300,000 cubic feet at the velocity of one and one-fourth miles per hour.

These surveys were also used as the basis of the larger improvement which was immediately defined and inaugurated after the opening of the channel in 1900, for a capacity of 10,000 feet per second.

That plan consisted in bascule bridges in the stream of a uniform width of 200 feet, and a central depth of twenty-six feet; and has also been carried uot in part with the cooperation of the United States.

The capacity of the Main Channel at the Rock Section was actually 840,000 cubic feet per minute.

The occasion for making further improvement in the Chicago River and its branches after 1900, by the Sanitary District, was to get the increased capacity which was required with the growth of population, after the initial capacity of 300,000 feet had been established, and to accommodate
1743 600,000 feet by way of the Chicago River, and later that was supplemented by the flow by way of the 39th street conduit.

That new improvment or the improvement after 1900 was known as the Chicago River Improvement Project of 1900.

If the flow through the Sanitary District Canal had been limited to 5,000 cubic feet per second after 1900, it would not have been necessary for the Sanitary District to have made the changes and alterations in the Chicago River that it subsequently did make after 1900.

1746 Amounts expended on Chicago River improvement:

Total expenditure up to and including 1899	$ 727,441.02
Expended in 1900,	837,165.39
Total expenditures up to and including 1900,	1,564,606.41
" " five-year period, 1901-1905,	6,727,708.34
" " up to and including 1905,	8,292,314.75
" " five-year period, 1906-1910,	2,082,229.92
" " up to and including 1910,	10,374,544.67
" " two-year period, 1911-1912,	266,194.85
" " up to and including 1912,	$10,640,739.52

The building of the Main Channel and the improvement of the Chicago River which is a part thereof has extended lake navigation to a depth of twenty-four feet, thirty-six miles from Lake Michigan and within a mile or two of the City of Joliet. Lake navigation has not yet developed on a scale of twenty-four feet, but is predicated for that depth by the new lock now under construction at Sault Ste. Marie.

Below the water power station at Lockport, navigation is extended by a lock constructed by the Sanitary District suitable for small boats down to Dam Number 1, at Joliet, two and six-tenths miles; and this channel is twenty feet or more in depth for most of the distance, and a limited depth of ten feet after it reaches the Des Plaines River and the upper basin at Joliet. Navigation by small craft can extend to Dam Number 1 at Joliet.

1747 The Sag Channel is of smaller dimensions than the Main Channel, and is available for barge navigation of any draft of barge which can pass under the bridges, such as has been repeatedly recommended by federal engineers, in connection with the route between here and the Mississippi.

At the end of the Main Channel near the power station, thirty-six miles from Lake Michigan, a location has been reserved for a lock of any dimensions that may be necessary or desired, by which the depths and capacity of the Main Channel can be extended down the Des Plaines River by future improvements thereof.

The jurisdiction of the Sanitary District, so far as producing channels for navigation is concerned, stops at the upper basin at Joliet. The state has projected from the end of the Sanitary Canal at Lockport at the waterpower station, under the report of the Internal Improvement Commission in 1907, and by virtue of the constitutional amendment adopted in 1908, a project by which the navigable depth available in the Drainage Canal can be extended to Utica over the rock-bound section and the high declivities of the upper Illinois River by means of five locks and four dams and the development of the pools between these dams. This project proceeds on the basis of twenty-four feet to the second lock at the head of Lake Joliet through the City of Joliet, where it is largely in rock cut. But from that point, the head of Lake Joliet to Utica, it proceeds on the basis of a preliminary depth of fourteen feet, to be deepened progressively as the needs of navigation shall require.

Further than that, there has been no actual legislative provision as far as the state is concerned. The state has expressed its policy in a number of resolutions and statutes, and the United States has been asked to cooperate to the extent of building the locks in that part of the river, under the constitutional amendment, between the water power station at Lockport and Utica, at a cost of about eight millions of dollars, and to make the improvement by dredging in an open channel in the Illinois River between Utica and the mouth of the Illinois River, a distance of 230 miles; and there provide a channel of a preliminary depth of fourteen feet, at a cost of about $8,000,000.

In other words, the proposition as it now stands is this: That the State of Illinois, by the Act of 1889, makes the Main Channel of the Sanitary District to the upper basin a 1748 navigable stream and gives the United States control of it whenever the river shall be improved below, and the Sanitary District has expended upon that and collateral works something like $80,000,000, and the State of Illinois has put itself in position, by act of the Assembly, to spend an additional $20,000,000 in extending, a total of about $100,000,000. And the United States has been asked to cooperate to the extent of providing $16,000,000; the effect of it all being to produce a waterway from Lake Michigan, 327 miles long, to the Mississippi River at Grafton, with all structures, and rock cuts in the same channel for a depth of twenty-four feet and a preliminary depth of fourteen feet in the river below the head of Lake Joliet.

Perhaps I may add in that connection that in the later consideration of the matter by the State after 1907, it is based on a flow of 14,000 second feet; and that the Deep Water Project is not practicable without the aid of the large water supply from Lake Michigan, which has been authorized by the State law.

Outside of that, we would be limited to eight or nine feet as the best that could be done.

These depths of fourteen feet were predicated by the original act and collateral legislation in 1889, and in all subsequent legislation, were based on a flow of 10,000 feet and the report of 1907 used that depth of fourteen feet as a preliminary depth, but states that with the aid of the 14,000 feet, it will be possible to continue twenty-four feet to the City of Peoria and twenty feet more or less from thence to the mouth of the river.

And I assume from the fact that the constitutional amendment was based on that report, that is the project. It is the one that has been advocated by the Lakes to the Gulf Deep Waterways Association, and the one that was presented to

Congress in the hearings of 1910, before the House Committee and before the Senate Committee, and Congress made conditional appropriation of a million dollars for the beginning of work, whenever an understanding should be reached with the State of Illinois regarding a plan of cooperation.

The Chicago River prior to this improvement was little more than an adaptation of the Chicago Creek, which 1749 was known before Chicago was here; and its capacity for carrying a flow of water was limited. It is difficult to make a comparison where the stream was so little adapted to the present purpose, and where the change has been so radical.

Originally the Chicago Creek carried twelve feet up to the Forks, and its original improvement, the first improvement, was based on a depth of thirteen feet, which was subsequently increased to sixteen, and the tunnels built under the river limited the use of the Chicago River to sixteen feet, until they were removed within a comparatively recent period. They were removed by the city at a very considerable cost, which should be added to the expenditure of the Sanitary District and the United States, in getting at the true cost of the improvement of the Chicago River.

When the Sanitary District entered upon the improvement of the Chicago River, it was approximately sixteen feet in depth.

The depth has been increased to approximately twenty-six feet, and that is the depth carried through the main channel, to the power house.

There were portions of the river that would run up to 200 feet and even 300 feet in width, and again other portions that were less than 100. The narrow portions have been widened, or are being widened, except a very limited area near the Pennsylvania Central Station, which has been greatly delayed.

It has been widened to a large extent throughout its entire length, the Chicago River and the South Branch, so much so that it could almost be considered a new river.

There were center pier bridges with openings varying all the way from sixty feet up, depending on the width of the river; and the openings have now all been made uniformly 140 feet or more, so that vessels can go down the center of the stream without interfering with vessels that are moored at the docks, whereas formerly with the old type of bridge, they had to crowd the dock line, making it unavailable, in order to pass through.

This increase of depth and width of the river and the changing of the bridges has been of very great benefit to navigation. Under former conditions the river in many places was so constricted and tortuous that boats of the model prevailing along in 1900, 476 feet in length or thereabouts, were unable to pass through the river.

Since then, we have had boats up to 617 feet in length which could pass through. The alignment has been corrected and the channel deepened to a limit of twenty-six feet for a width of 140 feet in the center and the bridges have been put in with that central opening, so that the river is now available for a type of vessels which could not be considered in the early history of the stream and up to 1900.

There has been a very substantial and material increase in the depths in the Des Plaines and Illinois Rivers. The lock and dam system built by the State between LaSalle and Havana provided for a depth of six feet on the mitre sills at low water of the Illinois River, and this low water has shrunk at times down to limits of 400 and 500 feet per second within the division that I am speaking of. The present flow of the Sanitary District would give six feet throughout all that reach above the plans of the old low water, to which you could add twenty inches for the depth existing under original low water. In other words you would have seven and a half feet under the natural conditions in the river between those points without the dams.

The Board of Engineers known as the Ernst Board, which reported in 1905, stated that with a flow of 4,200 second feet

it would be possible to obtain in the Illinois River a navigation considerably in excess of seven feet, without the aid of any dams whatever, and that there should be no objection to the removal of these dams.

It was examinations of these questions which led to the
1757 project of the State for an open river improvement in these parts without the aid of the dams.

The estimates which were made at that time, made largely by me and my assistants have proven to be conservative, and that we can obtain better navigation without the dams at Henry and Copperas Creeks, and the Federal dams at LaGrange and Kampsville, than we had supposed when the State fixed its policy in that matter; and that we can obtain the fourteen feet more readily than supposed, and obtain the twenty-four feet and the twenty feet which I mentioned above and below Peoria more readily than supposed.

The State dam at Henry was opened in 1871. The State dam at Copperas Creek was opened in 1877.

The Federal dam at LaGrange was opened in 1889 and the Federal dam at Kampsville was opened in 1893. They were all part of a project that goes back to 1866 and 1867.

Before the Sanitary District flow was established through there, at low water and at ordinary stages of the river, boats used the locks. At high water they passed over the dams without obstructions.

Not to be compelled to use dams of that kind, or locks, is a very great benefit on account of delays; on account of tolls charged at the State dam, though there is no charge at the Federal dam, and by reason of the fact that the capacity of the locks is limited and boats and barges and fleets have to be accommodated to the size of the locks. Boats without the dams today would come to LaSalle, and barge fleets would be made up there. They would not pass through the locks if the dams were absent.

1752 The Sanitary District has an estate between Robey street and Lake Joliet of between seven and eight thou-

sand acres; and under the law is permitted to develop dockage and utilize this property.

This property that the Sanitary District owns is adjacent to the channel and along the channel its entire length on both sides and was obtained for the purpose of facilitating the construction of the channel and the river diversion.

Taking the channel at thirty miles from Robey street, it really adds to the capacity of the Chicago Harbor and its potential value about sixty miles of dockage; and if the estate is developed further by slips, why the amount of dockage that can be thus developed is unlimited.

So that it would be possible to establish practically an inner harbor.

That is one of the propositions that has been held in view from the beginning, and was outlined in a report which I prepared in 1890, printed in 1891, that the Drainage Canal on its waterway site would be developed as an auxiliary to the Chicago Harbor, and that future industrial development would largely take place, by a natural evolution as the city expanded, alongside and down this channel into the state; and that view of the proposition was in harmony with sound public policy, as these growing industries with their wastes would thus be automatically cared for in the simplest and cheapest manner. So it had a double reason, both commercial and sanitary, for the development of a harbor and its appurtenances in that direction.

That was one of the reasons why the item was put in the bill permitting the district to develop that as incidental to its other purposes: In fact it was the view held in constructing these works that all collateral advantages should be utilized; all by-products that were possible should be cre-
1753 ated, with a view of mitigating the heavy tax burdens of the community. And I think that the Chicago Project in its entirety, involving the waterways and dockage and waterpowers and other things that it does is really the first example that we have in this country of a well considered,

scientific project of conservation, for all the collateral utilities are to be developed and utilized.

The Chicago & Western Indiana, which is the main Belt Road, crosses the channel near the city limits, between Robey street and Summit. And the Calumet Terminal, which is also a Belt Road crosses the channel a mile below Summit. And furthermore the E. J. & E., which is the Outer Belt Line, crosses our channel between the water power station and Joliet; and makes the channel accessible to the entire railway system. And in that connection, it may be remarked that the report of the Federal Officer at this point recommends the development of a certain amount of harbor facilities adjacent to the channel, in the vicinity of Summit.

These Belt Roads mentioned make it possible to bring all kinds of freight down to the Main Channel.

And makes it possible, if the channel is developed as I have indicated, to have arrangements for the interchange of lake and rail freight.

In my judgment the location of the Sanitary Canal is really the only practical and economical location for such an interchange about Chicago, the logical place for it to occur. It is centrally located with reference to our commercial facilities by rail. It is accessible directly by a number of the trunk lines, and this number is so large that it practically would do away with the switching charge for all the other lines and we would be rid of $5 to $8 per car on all reshipment business done at Chicago as at present.

On the other hand such facilities transferred more remotely to the South or North would subject the commerce of Chicago to that extra burden.

The Calumet-Sag Channel runs from the Main Channel 1754 at Sag, Illinois, to the Little Calumet River at Blue Island and is something over sixteen miles long from the mouth of Stoney Creek, at its junction with the Calumet River to Sag Station; about 17 miles from the beginning of the San-

itary Canal at Robey street, and about 13 miles above the power station at Lockport.

It runs through a natural depression or valley called the Sag Valley, which is only less adapted to the development of a channel than the territory along the main channel of the District. This route has always been regarded as a favorite route in official reports of the United States, and has been frequently recommended for development for purposes of navigation.

The United States has taken steps towards the improvement of the Little Calumet River for navigation up to the point where the Sag Channel will connect with the Little Calumet.

The Calumet River is already improved for a width of 200 feet and a depth of 20 feet up to what is called the forks or outlet of the Calumet Lake; and in the last Rivers and Harbors Bill, there was an item calling for a project for the improvement of the river up to Blue Island.

And that is the point at Blue Island where the Sanitary District Channel connects with the Little Calumet.

Under the plans laid out by the District, there will be free navigation into the Sag Channel from the Little Calumet River.

And free navigation from the Sag Channel into the Main Channel of the District.

Any boats that would pass through would be able to pass through the Sag Channel, where it has a depth of 20 feet the same as the improvement of the Calumet River. Mean-
1755 while, craft can all pass up this route to Blue Island. It only requires deepening to adapt it to deeper navigation. There will be no limitation on the capacity of boats passing through except the bridges.

Navigation by the construction of this Calumet-Sag Channel, under the plans which the Sanitary District has adopted, and under which it is now being constructed well be greatly aided.

The flow of water has been and will be of enormous benefit to the Illinois Valley for two reasons; the first of which relates to sanitary conditions and the other of which relates to the physical conditions attending upon the river itself, and the overflow lands.

In a condition of nature, the Illinois River had in dry seasons an extremely small volume, which was measured in 1867 as low as 633 second feet. The reclamation of the swamps, which constituted 1/3 to ½ of the drainage in some watersheds and the tillage of the uplands has greatly reduced the low water supply and greatly increased the load of detritus which the stream has to carry.

The Illinois watershed is also one of the richest watersheds of the United States in proportion to its area, and produces thereby an enormous vegetable growth which quite consumes the water supply that falls in the growing season, leaving practically nothing to run into the streams. It happens by reason of these conditions that the stream is incapable of taking on any considerable load of sewage from the cities and towns located along its banks.

Further the stream bed is rapidly depreciating on account of the detritus from the uplands. These conditions at times under an ice cover when the organic matters in the water depleted the oxygen supply resulted in the decimation of the fish crop. Nevertheless, even prior to the opening of the Drainage Canal, by reason of the use of the river as an outfall for Chicago sewage and the very considerable increase in the low water volume which was doubled by the canal, even the old Illinois and Michigan Canal in low water seasons in
the upper half of the river, this fish crop had grown to
1756 large proportions, reaching from six to eleven and even
14,000,000 pounds; and was the best fresh water fishery in the United States, but was not a reliable industry.

The introduction of the water from the Sanitary District in comparatively large volume multiplying the low water supply at LaSalle by ten times, the low water supply in the

lower river by six or seven times, the fish crop became a reliable industry and has reached a magnitude under the census of 1908 of about 46,000,000 of pounds, of all kinds. And the value to the fishermen had reached over $800,000, and double that to the consumers. This crop represented $10 per acre on all the water space of the Illinois River Valley, or has been otherwise expressed, that the annual output was equal to 50 cents a lineal foot for the river.

Some idea of the magnitude and importance of this industry may be gathered from the fact that the output of this single stream represents ten per cent of all the fresh water fisheries of the United States, 30 per cent of all the fisheries of the Mississippi Valley, and is equal to 25 per cent of the entire fish output of the Great Lakes.

I think it is a fair assumption, and is so regarded by our Fish Commission, and by the Natural History Survey of Illinois, that this fish crop is largely due to the use of the stream for sewage disposal. The plankton in the Illinois River at Havanna, which is the basis of fish food, have been under examination by the Natural History Survey of this state since 1894; and since the introduction of the water in 1900, they recognize that the plankton have increased about from two to three times per cubic foot of water. And in view of the fact that the average flow of the stream has or will be doubled at Peoria when the channel is operated to a capacity of 10,000 second feet, the plankton content of the Valley will be increased from four to six times, and the fish crop stimulated proportionately, so that it is likely to grow to far larger proportions than even the present output.

This matter of the fertilization of waters is a new thought to people who have not considered the matter, but has been practiced from time immemorial in the fish culture in China, and is a recognized method of producing fish products as much as fertilization of land in the older countries, in the oriental countries.

1757

On the other side of the question, in regard to the physical conditions in the Illinois River, we have below Utica a stream

230 miles long with only 28 feet fall, or less than an inch and a half to the mile. The upper half of the stream, down to Havanna, has less than an inch per mile. There are conditions in the Mississippi River when if the Illinois River were low, flood waters would set back clear to Utica, and the stream would be level. There are other conditions in which the Illinois River might be assumed to be in flood and the Mississippi River low, in which the slopes would be doubled.

These conditions make the reclamation of the bottom lands extremely difficult and the maintenance of the river itself as a drain under the increasing load of detritus also extremely difficult. The only salvation, and that has been recognized from the beginning of this project, for the lower Illinois Valley is to introduce into that stream a large supply of water, to remove the dams and deepen the stream by dredging so as to maintain a channel of a good depth with a positive current that will be self scouring.

That condition cannot be produced in nature because the heavy flows in the Illinois correspond more or less closely with the heavy flows in the Mississippi, and with a large supply of water introduced into the Illinois River when the Mississippi is low, we can maintain a scouring channel; and the presence of the dams in that river is not consistent with maintaining such a channel.

Some recent examinations which I have made respecting conditions in the Illinois River show that since the state dams were erected at Henry and at Copperas Creek, there has been a depreciation on the upper half of the river of 2½ feet in the depth of the water below the original low water line of 1867, as it was defined in that survey. In other words, the river bed below low water has shrunk already, between the surveys of 1867 and the Ernst Board surveys of 1903, by 30 per cent; and the bank-full capacity of the stream has diminished by 15 to 20 per cent.

Further examination of the stream lower down shows that the Federal dams have been instrumental in contributing to the depreciation of that portion of the stream, and the only

remedy is to make a better drain of the Illinois by deepening it, without the dams, and introducing therein a positive and a large flow of water.

1758 This is important, not only from the standpoint of maintaining navigation automatically, as it were, without maintenance from year to year; but is of absolute necessity from the standpoint of conservation in the reclamation of the bottom lands themselves, of which there are some 40,000 acres between Utica and the Mississippi River. So from this standpoint, not only the interests of sanitation, the interests of the salubriety of the Valley itself, which will become a morass if present conditions continue or if the natural conditions continue, but also in the interest of reclamation of the bottom lands, a deep channel with a sufficient supply of water to maintain a scouring current therein is an absolute necessity.

On the sanitary side, as respects the disposal of sewage in this stream, such disposal was intolerable under natural conditions of flow, practically impossible by reason of the fact already stated, that the waters are already highly charged with organic matter from the very rich watershed, and particularly in flood times more than in low water.

I have seen, when I was examining the river for the State Board of Health, the output at Peoria alone, and at Pekin, from the wastes of the population and the wastes of the industries at those points, produce a black water through which fish could not pass, all the way down to the Copperas Creek Dam, a distance of 25 miles, when the river resumed its normal appearance.

This was significant, not only as to the ease with which the industries and the limited population polluted the stream in its natural condition, but was also very significant in regard to the progressive purification of the stream, even with that limited volume of water.

It was a material consideration in the Legislation of 1889, not only from the standpoint of the State Board of Health but also from the standpoint of all the Valley cities that this water

which served Chicago would through its progressive purification be able to serve also all the future population that might exist in the Illinois Valley in urban communities; and that in making a provision here as we did actually make for a population of over 4,000,000, we could assume at least that that would care for an additional future population in the Valley of 1,000,000. So that the Sanitary problem, from the state's point of view and the forces that prayed in the legislation of 1889 was a mutual problem, not only for Chicago but also for the Illinois Valley; the two representing over 70 per cent of the urban population of the entire state. To deprive them of this water would force all the towns in the
1759 Valley adjacent to the Des Plaines and Illinois Rivers to resort to artificial treatment, at very large cost, whereas their problems are now cared for automatically and without cost to themselves.

The problem presented of the disposal of sewage of a large metropolitan population like Chicago and its environs, which is included within the limits of the Sanitary District of Chicago, is materially different from the problem presented in the disposition of the sewage of a small city.

In small cities, they are not endowed usually with the industries of the great towns nor are their sewage wastes disposed of to the same extent by the sewer system as is necessitated in the large cities.

Again, in large cities, dimensions and magnitudes increase with the distances that have to be covered, so that the cost of any solution increases faster than the growth of population; or is out of proportion, you might say, to the growth of population, as compared to the small town or to the average small city, rather.

Removing sewage so that neither an effluent nor the raw sewage nor the rain drainage from streets, etc., would reach the water supply of the city is the very purpose to be attained with the greatest degree that it is practicable to do so. Fortunately, here, we can reach an ideal limit in that respect.

Any proposition that does not absolutely exclude sewage and land waters from the water supply is unsafe, by reason of the fact that no process of artificial treatment as now advocated, or of filtration of water supplies, gives immunity from any pathogenic germs that may be in the water; and by reason of the fact that any laxity in management or care is liable to bring about contaminations of the water supplies upon which the people may be relying as entirely safe.

I do not regard any proposition in connection with a water supply as safe, that is not automatic, and that depends upon human agencies and solicitude, under the civil service conditions that prevail in American cities.

1760 The Chicago water supply, on the other hand, can be made absolutely automatic and absolutely free from contamination, and the disposal of sewage can be put on the same basis, so that we can go away and forget about it; have no fear as to the consequences.

It depends upon the action of no person; does not depend upon the whims of an appropriation bill, or anybody's action as to whether they are exercising more care and vigilance than is necessary, or any of those things,—human frailties, it is free from. And experience has abundantly demonstrated that whereas in the early stages of these artificial methods much was expected of them in the way of absolutely arresting germ life that was deleterious to health; on the contrary none of them are quite safe. Filters and bacterial beds may get seeded down with the wrong kind of germs, so that the water supplies have to be watched with extreme care.

I think the best illustration of that is the recent report on the Milwaukee conditions by a Board of Engineers that is partial to artificial treatment, where they gather up the supply at the southern limits of the city, and after treatment pump it out into the lake as far south from the water supply as practicable. Then after doing this, they have to provide artificial methods for circulating the waters in the rivers in order that they shall not become offensive; and after going to

all this cost, they find that it is necessary to filter the water supply. And then they proceed to say that filteration methods, and slow sand filteration is so uncertain that it will be necessary to watch the results very carefully, and to be prepared at all times to doctor the water with chlorine or some other preparation to kill any germ life that may ecape the filters.

I think that probably is as severe a comment as could be made respecting conditions as they have been worked out for other cities not so fortunately situated as Chicago.

Chicago is the only city situated about the Great Lakes in which sewage disposal can be made through the back lots, and in which even storm waters for long distances along the lake shore may be absolutely excluded from the lake itself, 1761 the source of water supply. The pass that we have to cut down to divert our waters to the southwestward is only 7 to 8 feet as measured by the rock floor at Lemont above the low water of 1847; and only 2 to 3 feet above the high water of 1838, so that a channel can be cut in that direction at a minimum cost.

On the other hand, the lowest divide to the east between the waters of the lakes and the Ohio River is the Wabash-Maumée Divide at Ft. Wayne, which is about 190 feet above Lake Erie. And on the north is the Fox-Wisconsin Divide at Portage, Wisconsin, between the Fox River that empties into Green Bay and the Wisconsin River which empties into the Mississippi River, and this divide is 210 feet above the lake. So it is not possible at any other point about the Great Lakes to make a solution at all similar to that which has been provided at Chicago.

It is one of the endowments of our site, and it is the reason we are here, and it is the reason that the city is here; and from my point of view we are entitled to avail ourselves of it like any other bounty of nature, and to utilize the lakes in that connection.

From a conservation standpoint we utilize the lakes in that connection for all the utilities that can be worked out of it. It

is perhaps the highest conservation to which waters have ever been put in the world.

The investigations of the Sanitary District and of the
1762 State Board of Health in 1885 to 1890 considered a number of propositions of sewage disposal which were then seriously advocated as alternatives, and which are now regarded as obsolete.

The matter of land disposal, which is the most effective of all these methods is usually regarded as prohibitive on account of the cost, and because it can only be resorted to in favorable localities; and it is now recognized that if the effluents are to be disposed of in streams where water is used for water supply, that even in this case they must be sterilized. That was one of the principal methods advocated in 1886 and 1887 as an alternative.

The other plan of sewage disposal in the lake would not now be considered, even with sterilization, as a proper solution under conditions where it was humanly possible to do anything else. The objections are that sterilizing methods are subject to all the human limitations involved in the management of other methods, and are liable to be inefficient; sterilizing fluids are not considered as particularly conducive to public health and that even after sterilization the decompositions go on; there would be a tremendous pollution of the lake bottom, which would be a nidus in which deleterious germs might reproduce at a later period. And in a condition of stirring up of the lake bottom by wings, would make a very unwholesome looking water, if it was not actually dangerous to the health.

As applied at Milwaukee, as I have already remarked, they do not consider it, even with chemical treatment, to be a tolerable treatment without also at the same time filtering the water supply, and even after that sterilizing the water supply, after it had been filtered, when dangerous conditions appear in such filtration effluents.

It is recognized that disease germs will pass through even filters that are used for the purification of waters that are not contaminated with sewage. Unhappily, they get seeded down at times with the wrong kinds of germs.

The third method which was considered but not reported upon, but however was much advocated at that time and appeared in bills before the General Assembly for consideration as alternatives were the methods of chemical treatment. The principal one of these was the scheme of Gordon H. Knott, which was endorsed by very influential men, including some engineers from Chicago, which contemplated a tunnel 20 feet in diameter to extend down to Joliet and there the sewage was to be treated and released to the Des Plaines River. The tunnel which was then projected would carry something like 1,000 feet of water per second, barely more than the present water supply of this city. It would not solve any of the other problems associated with the good health of the city; and
1763 the treatment of the sewage proposed by chemical means only removes from 30 to 40 or 50 per cent depending upon the character of the putrescible matter; so that the effluent somewhat stabilized would still go to the Des Plaines and Illinois Rivers, and in the known high condition of the organic matters contributed from the land would produce an intolerable condition and be an impossible solution.

The fourth method which has found advocates and was mentioned as an alternative in the St. Louis case is the method by septic tanks, which was developed however after our consideration here at Chicago. Abroad, it was known as the Cameron Tank Proposition, and originally contemplated decompositions without a supply of oxygen, or aeration, known as anaerobic, to be alternated with aerobic decomposition, or the presence of oxygen.

This is in effect the cesspool method, which through various appliances, or in the use of euphonious names is called a septic tank proposition. Everbody is familiar with the cesspool proposition as it existed before we had any method of sewage treatment, or any sanitary science, or where in the country

sanitary provisions have not been adopted according to the modern method. But it seemed to have taken on a highly scientific value when proposed by wholesale, in the minds of its advocates.

That was, to my mind, effectually disposed of at Chicago, so effectively that it ought never to have been advocated by anyone, because we had a septic tank on the largest scale possible in this world in the 64 acres of the South Fork; and we had it in the North Branch in an area of more than 100 acres, and the conditions produced were so totally intolerable and inadmissible that it always seemed to me an impossible method of solution for any considerable body of people.

There have been a number of works even in this state and in Indiana constructed on that plan, ten or twelve I think. I believe today there are only two of them in actual operation. So that method may be considered as having passed into disuse or having become obsolete, and it should never have been considered, in my opinion, in view of the conditions that were patent here at Chicago.

The later methods were an evolution from the experiments at Lawrence, in a large degree, and consisted of bacteria beds; first, what was known as the contact beds, consisting of a bed of stone in a tank from six to nine feet deep, which was charged with sewage a number of times each day, and it was in fact a bacteriological stock farm on a concentrated scale.

1764

The anaerobic decomposition was supposed to occur while the bed was filled with sewage, and then the water was allowed to drain out and was supposed to give place to the aerobic decomposition, and this was much practiced up to a recent time, but is now considered obsolete, or not exactly obsolete but is discarded for a method considered to be superior, which is the percolating beds, so called sprinkling filters, which also consist of a bed of stone or other material; it is also a bacteriological stock farm, and in which the decompositions are entirely aerobic, except that it is usually

recommended that some sedimentation be given in advance and a slight septic condition produced by ten to twelve hours in the tank before it goes on to the bed. That is the last remnant of the septic tank proposition.

This method is the only alternative, a survival of all the experimental methods that have been tried out in the last forty years, and it may be said that no alternative that has ever been suggested for Chicago up to this time has proven up in practice, even for a moderate sized city, much less a city of this magnitude.

The method of nature in the percolating filter proposition, in fact in all methods that are practiced is the oxidation method, precisely the reactions which occur by dilution except in the dilution method the gases are absorbed and the operation is without offense; and the danger from the passage of pathogenic forms is probably much less.

All these methods in early times and up to a very recent time were presumed to dispose of the pathogenic germs, but it is now recognized that even the percolating filter does not do that, and that it must be followed by sterilization if the effluent is to be put into any possible source of water supply.

In regard to the chemical treatment, that is practiced still to a limited extent in the outfalls at Manchester and at London, for the purpose of getting rid quickly of a certain unstable element in the sewage, which they throw down as sludge. In the case of London, this sludge is put into tank boats and 7,200 tons a day are taken out and dumped into the sea.

In the case at Manchester, they carry on their purification by bacteria beds and chemical means; mostly by bacteria beds, and remove the sludge to the sea, in order to save the conditions in the Manchester Ship Canal as far as possible from becoming a nuisance. And they even go so far as to purify the storm water and run that through beds also. I went over the Manchester Canal in the autumn of 1909, 1765 when the temperatures were moderate and rode from

Salford down to Liverpool on a sludge boat that was taking out a cargo of sludge to sea, and the Manchester Canal, with all the efforts made in the communities about the Manchester Ship Canal, to purify the sewage outflow before it was put into the canal, was not what I would call in a tolerable condition at all. So that what they consider a measure of success over there in regard to the purification of sewage, I do not think would be looked upon here as a tolerable condition.

I will say that in regard to the subject of efficiency, there is no method at the present time available that can compare in efficiency with the method which we have adopted here at Chicago; and there is no alternative which could be adopted which would give us a water supply of any character approaching that which we may enjoy in connection with the dilution method.

I would say further that all these artificial methods are very costly in operation and maintenance, whereas the method here is automatic in action.

I will say further that with the possible exception of Berlin none of these methods make any returns against operating expenses, and even in the case of Berlin it is contributory rather than in any sense a profitable investment, whereas in our case I look upon the conduct of the sewage effluent and its purification on its way to the Illinois Valley as having produced the most successful and profitable sewage farm that has been produced in the world, to the fish product in the Illinois Valley; and that we have really here the only tried out and completely successful proposition in the world.

At the time that we proposed the Chicago proposition, it was looked upon by a large part of the sanitary and scientific world, who admitted their own superior achievements and attainments, as a barbarous one. I think the sentiment in that respect throughout the world has radically changed, and that dilution methods are now regarded as the best and the proper method wherever water supplies are adequate for such a purpose.

I wish to add to that, as a tribute to our own foresight and sagacity, that we are far ahead today of the other parts of the United States and the rest of the world in regard to this subject of sanitary treatment as we were when Mr. Chesbrough projected the sewer system in 1855. And I believe if we had been able—this I consider very unfortunate for Chicago—to have worked out all the results and made a rec-
1766 ord such as should have been made of the investigation that preceded and accompanied this work that it would have been regarded as a monumental achievement and revolutionary of the whole thought of sanitary engineering at the time; and would have changed the public thought, scientific thought in the matter as completely as it was changed along in the forties when the filth theory of disease originated.

I refer to Mr. John D. Watson's report (of Birmingham, England) to the Metropolitan Sewage Commission of New York dated January 31, 1913, wherein in discussing the various methods of sewage disposal for the city of New York, he says (page 30 of book entitled "Preliminary Reports on the Disposal of New York's Sewage, Number VII"): "What influences me most in favor of scheme 4, is the conviction that where it is possible to remove the bulk of the sewage of New York entirely away from its source to the ocean, it should be so removed, although the cost may be somewhat higher than it would be under a project like Scheme 3."

The Metropolitan Sewage Commission of New York was constituted a number of years ago for the purpose of studying the conditions and remedies therefor around New York Harbor and Bay; and it has projected four principal schemes or alternative methods for the treatment of the conditions at New York, which are discussed by Mr. John D. Watson, engineer for the Borough of Birmingham, England, and also by Doctor Fowler, who is in the same position in relation to Manchester, England, which are usually regarded as the highest development of artificial methods of treatment.

The 4th method, which is the one endorsed by both Mr. Watson and Mr. Fowler, is estimated to cost about $100,000,000, and is substantially a dilution method so far as the same can be applied to the New York conditions. It consists of interceptors for the purpose of gathering up the sewage; conduits for conducting the same to a common outlet, and pumping works. And an artificial island is to be created in the sea opposite Jamaica Bay and out beyond the entrance of New York Harbor; and the sewage conducted to this point and released on the outgoing tide, with only such treatment and screening as are necessary to operate the pumps and the system as a whole.

1770 There are no currents in the lake except those induced by the winds, and they change with the changes in wind direction.

With the Calumet River reversed as it will be when the Calumet Sag Channel is completed and in operation, and the Main Channel of the District and other works in op-
1771 eration, as is provided by the Statute of 1889, and the project as now operated, I do not consider that there will be any pollution of Chicago's water supply from cities like Waukegan or other cities near or around the City of Chicago.

I cannot conceive of conditions which would bring currents of waters from that distance to opposite the mouth of the Chicago River, for instance. The probability would be so extremely remote as to be a vanishing quantity.

All our intakes are substantially this side of the Evanston line on the north and opposite 67th street on the south, and under such conditions, there would be no sewage effluent going to the lake nearer than Michigan City or nearer than Waukegan. There is just the possibility that under contingencies that might occur in an occasional year we might get a little pollution from as far as Waukegan; but I assume that the conditions at Waukegan will be remedied as they already have the authority to organize a sanitary district on their own account at that point. Certainly with

that done, I see no possibility of sewage pollution as affecting the water supply now taken at Chicago.

I think that after the beams are all out of our eye, we are bound to go after the moats that come from that source, and there should be some regulation that will prohibit steamers from dumping their wastes into the lake within a reasonable distance of Chicago.

Frederic P. Stearns, a witness for the defendant, whose qualifications have been heretofore stated (This Narrative p. 134), testified, July 26, 1913 (Vol. II, p. 1044):

The situation is extremely unfavorable for any other system of sewage disposal than that which the City of Chicago now uses. It is impracticable to obtain a water supply for the city from any other source than Lake Michigan, and in no other way can the water supply taken from the lake be as well protected from contamination as by the present general method of sewage disposal, which not only keeps the sewage from entering the lake but creates a constant tendency to draw from the lake any water that may become contaminated along its shores, and it keeps from the lake the necessarily contaminated water of its rivers.

1049 It is therefore in my judgment impossible for the Sanitary district of Chicago to reproduce by any other method of sewage disposal than that now used with the right to take from Lake Michigan the quantity of water, commensurate with the needs of the District from time to time.

1058 I believe the method in use is by far the best method; and I think it is also the only practicable method, practicable and efficient method of taking care of the sewage and protecting the water supply; but there may be some combinations of purification, or there may be some partial purification of the sewage which could be used in connection with the present method. But I do not see how the present method

could be abandoned, or greatly restricted in the quantity of water, and obtain results that should be obtained.

1077 I do not favor the discharge of the sewage of a great population into a lake from which a water supply is to be taken, in any case, without purification of the water supply; and even then I would place the intakes of water supply far from the place where the sewage is turned into the lake,

1078 if it were necessary. But it is very much better from a sanitary standpoint that neither the sewage nor the effluent should go into the lake.

Henry C. Adams, a witness for the defendant, whose qualifications have been heretofore shown (This Narrative p. 159; September 25, 1913), testified as follows (Rec. Vol. III, p. 1355):

I have made examinations of the records of the City of Chicago as to death rates from various diseases in the last twenty-six years.

Adams Exhibit 1 shows this computation, as follows:

1360

2—CHICAGO.

Death rates per 100,000 of population.

Years.	All Causes.	Typhoid Fever.	Diarrhœal Diseases.	Tuberculosis.	Pneumonia.	Bronchitis.	Influenza.	Diphtheria and Croup.	Scarlet Fever.	Tuberculosis of the Lungs.	Measles.	Whooping Cough.	Small-pox.	Bright's Disease.	Heart Disease.	Cancer.	Violence.	Tuberculosis other than Pulmonary.	Children under 5 years.

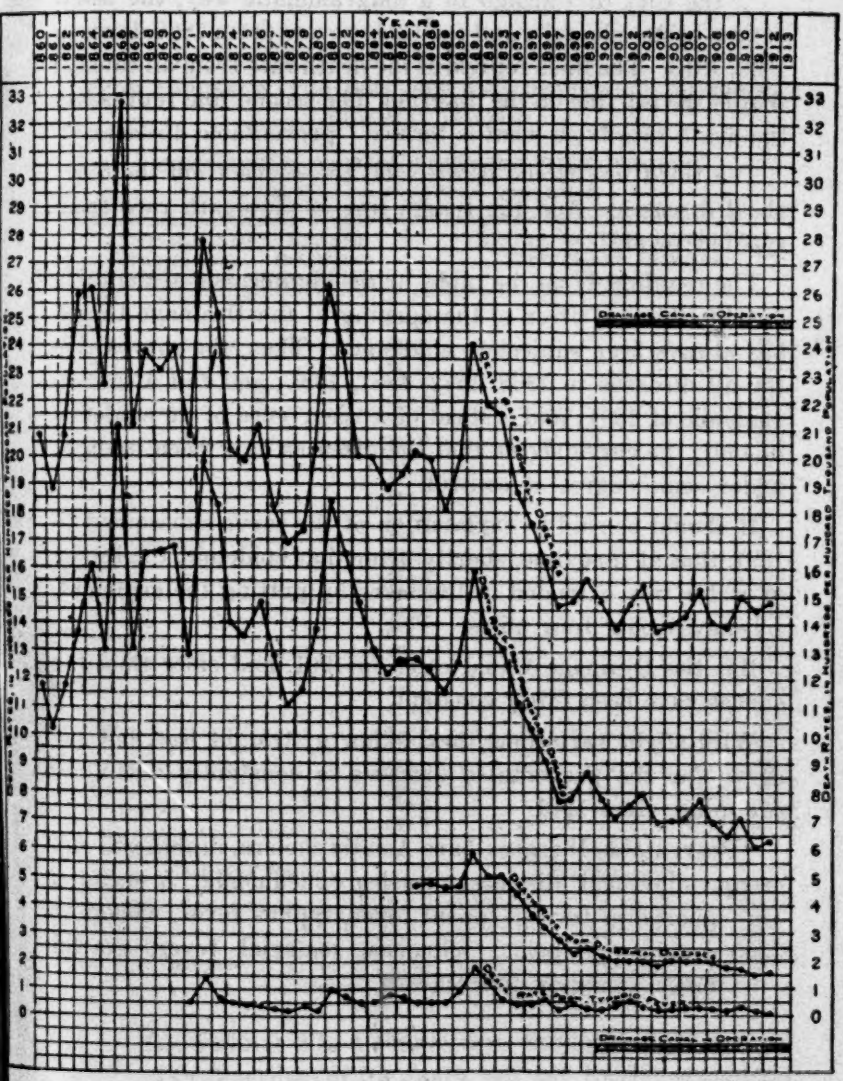
1361 The water-borne diseases are the typhiod fever and the diarrheal diseases, intestinal diseases in general. The impure air diseases are tuberculosis, pneumonia, bronchitis, influenza, grippe, and things of that kind.

1362 The decrease in the water-borne diseases is 56.9 per cent and the decrease in the air-borne diseases, computed in the same way, is 6.1 per cent.

1363



ADAM'S EXHIBIT 2.

1364 This table, Adam's Exhibit 2, presents the death rate in the City of Chicago in a diagrammatic way, the usual curves being adopted; and the table covers from 1860 down to 1912, 1913. The lines represent the death rate from all causes; that is the top line on the diagram. The second line represents the death rate from what is termed "preventable diseases."

The third line is the death rate, the curve from the diarrheal diseases. And the fourth line is the death rate from typhoid fever.

The readings from the table, or the significance of the table is that Chicago, prior to the opening of the Drainage Canal, has always been subject to epidemics. Thus, the curves rise for all diseases to 1866, 1872, 1881, 1891; and fall after the epidemic of 1891; and instead of a recurrence of an epidemic in 1901, the curve shows that the diseases have been brought under some degree of control.

It should be said in explanation of the curve subsequent to 1891, that at that time, shortly after that epidemic, the intake of water was extended in the lakes by putting the cribs out, I believe about four miles.

But the Drainage Canal came in 1901, and since then the curves have been fairly constant.

With slight variations they follow a straight line, but the curve for the preventable diseases is constantly declining, dropping, since 1901.

"Preventable Diseases" are Asiatic cholera, diphtheria and croup, diarrheal disease, measles, pneumonia, bronchitis, puerperal fever, typhoid fever, typhus fever, whooping
1365 cough, erysipelas, influenza, malarial fever, scarlet fever, smallpox, tuberculosis.

ADAMS' EXHIBIT 3.

6.

COURSE OF THE DEATH RATES

FROM IMPURE WATER DISEASES AND IMPURE AIR DISEASES

CHICAGO, 1887-1912.

COMPARISON OF TWO THIRTEEN-YEAR PERIODS.

Death-Rates per 100,000 Population.

Year	IMPURE AIR DISEASES (Tuberculosis. Influenza.) (Pneumonia. Bronchitis.) Total	IMPURE WATER DISEASES. Typhoid and Diarrheal Diseases.
1887	434.5	527.6
1888	441.5	533.9
1889	393.4	514.0
1890	508.7	563.1
1891	593.1	758.1
1892	515.6	623.7
1893	525.7	566.1
1894	401.5	483.0
1895	447.8	410.6
1896	419.6	389.8
1897	386.8	307.5
1898	422.7	282.3
1899	471.8	280.7
1900	447.8	236.0
1901	403.4	240.4
1902	416.8	245.5
1903	495.9	226.4
1904	454.3	197.3
1905	424.3	209.4
1906	436.8	215.5
1907	479.4	213.6
1908	407.6	218.1
1909	416.1	183.7
1910	433.2	190.9
1911	394.8	157.9
1912	391.4	157.2
	Average Rate.	Average Rate.
1887-1899	458.7	480.7
1900-1912	430.9	207.1
Decrease	27.8	237.6
Per Cent Decrease	6.1%	56.9%

This Exhibit 3 is a comparison for the two periods al-
1366 ready described of the death rate per 100,000 population from impure air diseases and the impure water diseases. The percentage result of that comparison has already been given.

The average decrease in the death rate for impure air diseases is but 27.8 per 100,000 population, whereas, for the impure water diseases, the decrease on a comparison of the average for the two periods, is 237.6, showing a decrease of 6.1 per cent in the impure air diseases and 56.9 per cent in the impure water diseases.

It is a well established fact, as shown by the statistics of cities before and after the introduction of the improvement of water supply, that the decrease in the death rate of the particular diseases held in mind, and usually this is typhoid fever, is accompanied by a corresponding decrease in the death rate of other diseases. And typhoid fever is commonly accepted as the basis from which to measure the general effects of the improvement of the water supply.

This relationship is what is known as Hazen's Theorem or Hazen's Law. It is universally conceded that the improvement that is reflected in typhoid conditions must be multiplied by some figure in order to get the general improvement in the health conditions of the community.

Here is a statement of Hazen's Theorem as given by himself, he says: "Where one death from typhoid fever has been avoided by the use of pure water, a certain number of deaths, probably two or three, from other causes have been avoided."

All my information on this point is taken from an article by W. T. Sedgwick, who is Professor of Biology at the Massachusetts Institute of Technology, and J. Scott McNutt, Health Officer, New Orange, New Jersey, published in the Journal of Infectious Diseases, 1910.

Professor Sedgwick is a recognized authority upon this
1367 matter in the United States. It was for the purpose of testing the accuracy of Hazen's Law that Sedgwick and McNutt undertook this investigation in American cities.

ADAMS' EXHIBIT 4.

Distribution of Deaths from Typhoid Fever, by sex and age. Chicago, 1912.

Age	Males	Per Cent of all Deaths of Males	Females	Per Cent of all Deaths of Females	Both Males and Females	Per Cent of all Deaths
1- 5	5	4.27%	4	6.8	9	5.1
5-10	5	4.27	7	11.9	12	6.8
10-20	18	15.4	13	22.0	31	17.6
20-30	42	35.9	20	33.9	62	35.2
30-40	22	18.8	10	16.9	32	18.2
40-50	18	15.4	2	3.4	20	11.4
50-60	5	4.27	1	1.7	6	3.4
60-70	2	1.7	1	1.7	3	1.7
70-80			1	1.7	1	.6
All ages	117	100.0	59	100.0	176	100.0

Males constitute 66.5% of all deaths, females 33.5%.
(Data taken from the records of the Chicago Department of Health.)

This exhibit shows the distribution of deaths from typhoid fever by sex and by age. The sex classes are under 5,
1368 from 5 to 10, from 10 to 20, from 20 to 30, from 30 to 40, from 40 to 50, from 50 to 60, from 60 to 70, from 70 to 80.

The third column of the exhibit shows the percentage of the total diseases borne by males at the various ages named. The significance, or the bearing of the table upon the question of the loss that might be suffered by a city in the absence of proper preventive causes for typhoid fever is that a larger percentage of diseases from typhoid fever is suffered by males than females; and that the age when typhoid fever is likely to result fatally for males is between the age, as shown here, between the age of 10 and of 60. Closer figures will show that between the age of 17 and 18 and 55 66-5/10 per cent of all deaths are male and 33.5 female. The figures here are taken from the records of the Chicago Department of Health.

I would add that the figures in this exhibit influenced me in choosing the multiplier in the application of Hazen's Law.

ADAMS' EXHIBIT 5.

II.

DECREASE IN VARIOUS DEATH-RATES SINCE THE DRAINAGE CANAL WENT INTO OPERATION.

Comparison of Two Thirteen Year Periods: (1887-1899) and (1900-1912)
Death-rates per 100,000 Population.

CAUSE	Decrease in Death-rate (1887-1899) (1900-1912)	Per Cent Decrease (1887-1899) (1900-1912)	Number of Deaths Prevented from cause named for every death Prevented from Typhoid
All Causes	398	21.3	9.3
Preventable Disease	418	36.9	9.8
Impure Water Diseases (as recognized by Chicago Dept. of Health)	274	56.9	6.4
Impure Water Diseases (as recognized by Sedgwick MacNutt)	*290	31.8	6.8
Diarrheal Diseases	231	55.2	5.4
Typhoid Fever	42.7	68.2	....

*1887-1899 compared with 1900-1912.

This exhibit is one designed to show the decrease in the
1369 various death rates since the Drainage Canal went into operation; first, from all causes; second, from the Preventable Diseases, and third, from the impure water diseases, as recognized by the Chicago Department of Health. Fourth, from the impure water diseases as recognized in the work of Sedgwick and MacNutt. Fifth, the diarrheal diseases. Sixth, the typhoid fever.

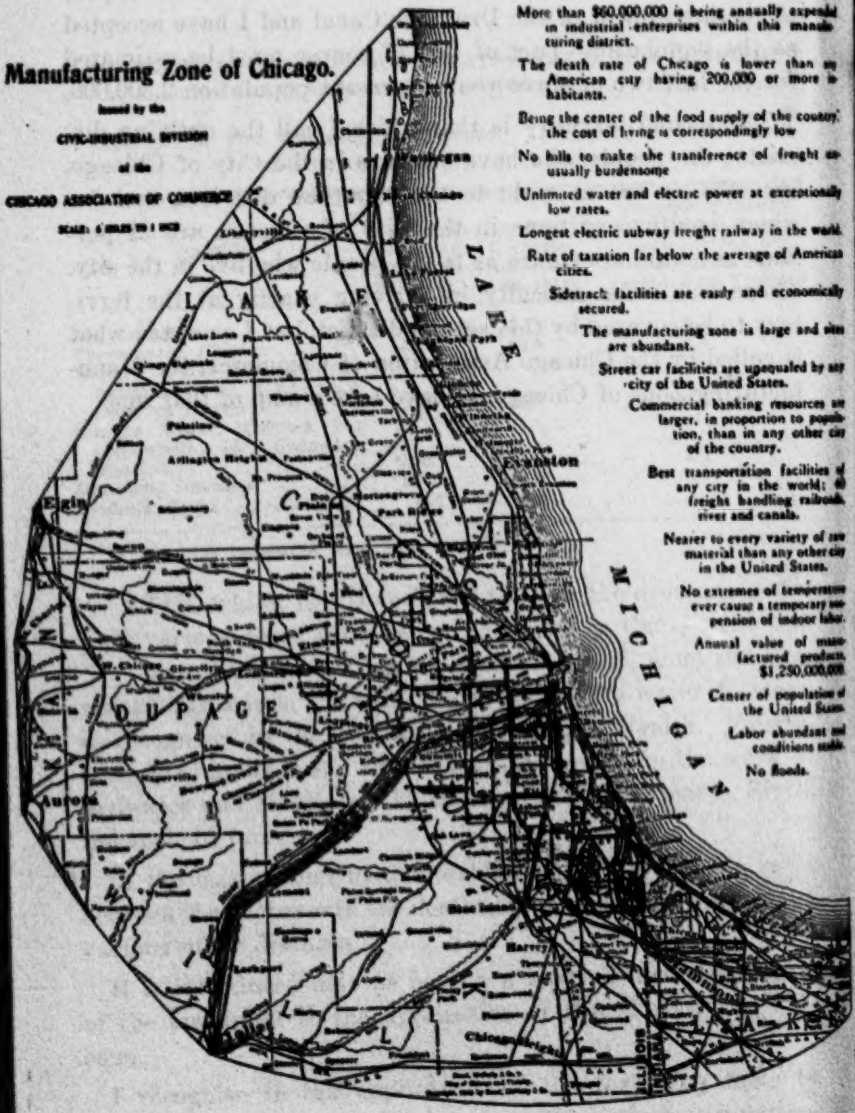
In the last column in that exhibit will be found the ratio between the decrease in the deaths from typhoid fever and the various other diseases.

It is introduced also as having a bearing upon the choice of the multiplier in the application of Hazen's Law to Chicago.

I recognize in the application of the foregoing facts to Chicago at least three territories with distinct population. The first is the municipality of the City of Chicago. This is

the narrowest possible conception of Chicago as a center of population. This is the unit that has bonded itself for part of the investment of the Drainage Canal and I have accepted as the population—part of this of course must be estimated for the last two or three years—present population 2,300,000.

The second territory is that which I call the outlying districts; the people who have business in the City of Chicago, but who go out at night to the suburban districts, and for whom health conditions in the City of Chicago are of perhaps as vital importance as to the people who live in the city. There was some difficulty in arriving exactly at the territory to be covered by this second district, but I accepted what is called by the Chicago Association of Commerce, the Manufacturing Zone of Chicago. I have here a map of that zone.



Manufacturing Zone of Chicago.
Issued by the
CIVIC-INDUSTRIAL DIVISION
of the
CHICAGO ASSOCIATION OF COMMERCE
SCALE: 4 MILES TO 1 INCH
More than $60,000,000 is being annually expended in industrial enterprises within this manufacturing district.
The death rate of Chicago is lower than any American city having 200,000 or more inhabitants.
Being the center of the food supply of the country, the cost of living is correspondingly low
No hills to make the transference of freight unusually burdensome
Unlimited water and electric power at exceptionally low rates.
Longest electric subway freight railway in the world.
Rate of taxation far below the average of American cities.
Sidetrack facilities are easily and economically secured.
The manufacturing zone is large and sites are abundant.
Street car facilities are unequaled by any city of the United States.
Commercial banking resources are larger, in proportion to population, than in any other city of the country.
Best transportation facilities of any city in the world; all freight handling railroads, river and canals.
Nearer to every variety of raw material than any other city in the United States.
No extremes of temperature ever cause a temporary suspension of indoor labor.
Annual value of manufactured products, $1,250,000,000
Center of population of the United States.
Labor abundant and conditions stable.
No floods.

The factors employed in computing the community loss
1399 on account of premature death as working citizens are,
first: the number of working years annihilated by premature death. For any given person this is measured by the difference between the age at which death occurs and the normal expectation of life for that age. For the community, the average at which death occurs is the point from which the measurement is taken.

The second factor is the worth or value to be imputed to a working year. By the first, it is evident that we learn the
number of working years for each year annihilated by a
1400 premature death. If now we know the value to the com-
munity of a working year, the multiplication of the one into the other gives the desired result.

That is well established by actuarial methods. And in the case of typhoid fever, which is made the basis of this computation, the loss, the average age of those who died of typhoid fever is 29 and a fraction years. Now, the average expectation of life for that age, 29, is 66 years. If now we take 65 as the limit of working years, there is by a death of typhoid fever annihilated the difference. At that age there is an expectation of 36 working years for each person that dies. Therefore, the deaths multiplied by 36 years gives the loss to the community in years.

Now, the other element the value of a year is one that the actuaries have always dodged. They have made assumptions, but have never given the matter, in my judgment at least, sufficient analysis, industrial or economic analysis.

I have for the purpose of this case endeavored to analyze the community's interest in premature deaths. And by the community's interest I mean the interest of the community as though the community were a unit, an organization, an industrial corporation, you may say, of perpetual life. And starting from that point, the burden that must be placed upon current industry is the burden first of maintaining the current social asset, the important asset being in the number of

workers in existence, so that notwithstanding deaths there will be births, raising children, education of workers, who will come to supply the place of the worker so that what you may call the labor asset of the community will be maintained.

Every time there is a premature death, the community loses in this respect; that is, the fund for the maintenance of its industrial or social aspects is impaired.

It is also a burden or a duty imposed upon current industry to provide for the normal development of industry, the normal growth of society, increase in numbers and increase in grade, quality of labor, greater education; and that I call as distinguished from maintenance of development, the additions and betterments that come to this society, considered as an industrial organization. Those are the two elements that are attempted to be measured; and each of them is impaired by a premature death.

Then, third, there is a dissipation of assets, a dissipation of energy, dissipation of well being, dissipation of work,
1401 dissipation of time, on account of sickness and death, and the cost of the sickness being a burden upon the community, a burden eliminated if there were no sickness, and this class is recognized as the third element of loss. Those are the three elements on that side of the equation.

ADAMS' EXHIBIT 13.

19

Loss that would be sustained by the City of Chicago and dependent populations were the present facilities for obtaining an adequate supply of pure water impared or destroyed, based upon a comparative study of health statistics of the city for 13 years before and 13 years after the opening of the Chicago Drainage Canal.

Per Annum.

Per 100,000 of the Population.

Kinds of Loss	From Increase in Typhoid Fever	From Increase in Other Diseases
I. By Loss of Contribution to Maintenance:		
a. Through premature death of workers, 83% of 28.39x36x300..	$254,488	$636,220
b. Through sickness, 83% of (484x10) + (28.39x2) + 52x300	23,400	23,400
II. By Decrease in Capital Building:		
a. Through premature death, 42.7x36x40	28,256	70,640
b. Through sickness (726x10) + 52x40	5,581	5,581
III. By Unnecessary Dissipation of Resources:		
483x58.41	42,405	42,405
	$354,130	$778,246

$354,130x23=$ 8,144,900.

$778,246x23=$17,899,658, which is the annual loss to the City of Chicago.

In the same way and for the same reason that a corporation 1402 sustains a loss, a railway corporation sustains a loss in case its locomotive is wrecked ten years before its life has expired. It also must use its resources to supply the place of that locomotive. But the resources used to supply the place of the locomotive that is prematurely retired cannot be used in any other way. I think the analogy between a corporation maintaining its property and improving its property and a community maintaining its labor force and extending its labor force is very close.

Under the first item mentioned in the table, namely, "By loss of contributions to maintenance," there are two subitems, *a*: "Through premature death of male workers" and

b: "Through sickness." The formula for computing the loss through premature death of male workers is as follows: 83 per cent of 28.39 multiplied by 36 multiplied by 300. The 83 per cent of what will be the result of the computation 1403 following that figure in the formula is arrived at in this way: this computation rests upon the loss incident to the premature death of active workers, and it would therefore be improper to include all of the deaths as the computation should confine itself to the deaths from typhoid fever that occur during the working period.

Now, about 83 per cent of the deaths from typhoid fever occur within the working years, and for that reason only 83 per cent of the 100 per cent of computed loss is permitted to enter into the present computation.

The table upon which that percentage rests has already been submitted as Exhibit 4.

The figure 28.39 is derived as follows: as already explained, the decrease in the number of deaths from typhoid fever per 100,000 population since the introduction of the Chicago Drainage Canal is 42.7; this decrease being arrived at by a comparison of the average number of deaths per 100,000 population for the 13 years prior to the opening of the Drainage Canal with the corresponding figure for the 13 years subsequent to that event.

Now, the table of distribution of deaths from typhoid fever shows that males constitute 66.5 per cent of all deaths. The decrease in the number of males dying from typhoid fever, therefore, is 28.39 per 100,000 of population. That means in effect that the deaths of females are thrown out in this computation, although there are some reasons why females should be included in the productive population, as well as males. But here, as everywhere throughout the computation, I have taken the lowest of the figures that can be used.

The figure 36 is the computed expectation of working life at the average age of death from typhoid fever. This average age for the City of Chicago including all deaths at all

ages, is 29.04 years. The average expectation of life for that age is 37 years. If now 65 years be accepted as the average limit of the normal working period, it follows that the number of years lost to a community, of working years, resulting from a death caused by typhoid fever is the difference between 29 and 65 or 36 years.

That next item in the formula is 300. This figure covers that portion of current earnings, the expectancy of which is for a communal or community purpose described in the foregoing analysis. That rests upon the assumption that the general average income representing the productive ca-
1404 pacity of workers is some $700 a year. We are concerned here not simply with workers, men who get wages, men on payrolls of factories, but it is all members of the community, and really you should take into account men who earn from a dollar a day up to men of very high income, all of whom are subject to death from typhoid fever.

The amount that is required for the support of the worker, what you may call the personal expenditure of the worker is deducted from what is called the average productive capacity of individual citizens, and the remainder is accepted as the community loss on account of premature death. That is, the remainder measures the amount that is contributed from the income of the worker to the maintenance of the working fund, and the expense, the personal expense, the demand for or the occasion of that expense dies with the man, but to the extent that while a man is living he contributes to what is the community need, namely, the maintenance of the number of workers, the education and rearing of working men so that they can take the place of workers when retired on account of age, that is the community contribution of the individual, and that community contribution of the individual is what is destroyed by a premature death.

I have put it here at the low figure of $300, on the basis of a $700 income. There has been a great deal of analysis and work by economists in arriving at those figures. I do not

care to go any further into that unless it is desired that I should do so.

1405 On the particular question, namely the estimate of productive ability, perhaps the best authority is Dilfredo Tatreto. He has made a study of the distribution of incomes, and has established what some regard as law of the distribution of incomes, so that if it is known, according to his law, if it is known what the daily unskilled wage is, he can arrive at the average of the incomes from $300 up to $30,000.

1406 Men like Hoffman usually take $600 as the earning capacity and merely say that the earning capacity is equal to the productive ability of the worker; but that includes only the day workers, the unskilled and the low paid workers. And that rests upon the statistics of wages which are very voluminous and very carefully worked out. This law arrives at an income, not only for day workers, wage workers, but for others who create their own wages, pay themselves their own wages, and there the average would be according to this law for a dollar a day something like $700 or $800. I took the lower figure and estimated the amount of personal expenditure, and the difference is recognized as the loss suffered by the community on the occasion of the premature death of any citizen.

The second formula presents the loss on account of cases of typhoid fever which did not result fatally. The 83 per cent is arrived at in the same way as in the first formula described. The figure 483 represents the number of male cases of typhoid fever which occur annually in the City of Chicago, but which do not result fatally. It is arrived at by the multiplication of the number of deaths, 28.39 by the figure 17, which is the figure accepted as representing the number of cases of typhoid fever for every death from typhoid fever. My authority for that figure is the Pittsburgh Survey, and Whipple on Typhoid Fever.

The figure 10 is the number of weeks that each case that recovers is out of work. That assumes that the sickness and convalescence in every case covers at least 10 weeks; I mean that is the average of the cases.

The 28.39 in this formula has already been explained, this being the number of deaths, and the 2 is the number of weeks on the average prior to the time that the death occurs, which is a burden for the community in the same way that the weeks of sickness of those that do recover. This is divided by 52 to reduce it to years and multiplied by 300, which is the figure in the formula already described.

The second kind of loss is expressed in the table as a loss by decrease in capital building. That is, every worker, every member of an industrial community, during his active life, not only contributes to his own maintenance but contributes something to the fund of which he is a part and to take his place when he dies; he not only does that but he contributes something toward the increase of the working fund and towards the higher education, which is equivalent to the raising of the quality of labor. This is the same thing as additions and betterments in the case of an industrial corporation.

This also is submitted under two heads: *a*, loss through
1407 premature death, and *b*, loss through sickness. 42.7 in the first formula has already been explained. I ought to say before explaining these figures that in this case it is population as such that is taken into consideration, because we only know the increase in wealth and capital on the per capita basis, and therefore it is not the deaths of workers, the working age, but the total deaths from typhoid fever that must be considered.

Now the 42.7 in the equation under A is the average decrease in the death rate from typhoid fever during the 13 years subsequent to the introduction of the Drainage Canal as compared with the 13 years prior thereto. This is multiplied by 36, because this loss continues for 36 years. And the loss per year is computed at $40 on the authority of the United States Census that the increase in capital or valuation from year to year is about $40.

There is also added here a loss because of the decrease in capital building through sickness, which is 726 multiplied by

10 divided by 52 multiplied by 40, all of which figures explain themselves.

The third point in the formula is losses by unnecessary dissipation of resources. That is what is commonly called the sick loss. And I have taken 483 cases of typhoid fever that do not result fatally, and I have taken the result of the Pittsburgh Survey, giving 58.41 per case. That seems to me to be unusually low, and so far as I know it is the lowest figure that has ever been arrived at, and I think is too low, for the reason that this Survey in Pittsburgh had to do with the poorer people in the poorer districts, whereas, the question we are now interested in covers all citizens of Chicago, of all classes.

The figure 90 has been suggested but the figure 58.41 is the one that is used in this computation.

I think that explains everything in the table, except the question of multipliers. The character and need of Hazen's Law has already been explained, and this table accepts 2½ as the multiplier; that is, it accepts the Hazen Law, as originally stated, and not as modified in figures by Sedgwick and McNutt and others, who place a higher figure.

Isham Randolph, a witness for defendant, whose qualifications have been heretofore stated, testified as follows:

February 23, 1898, the Committee on Rivers and Harbors of the House of Representatives, U. S. Congress, inspected the Sanitary District works.

May 5, 1898, Russel A. Alger, Secretary of War, and Gen. John M. Wilson, Chief of Engineers, in company with the Governor of Illinois and the Board of Trustees of the Sanitary District, inspected the works and the main channel then constructed. (Rec., Vol. VI, p. 3591-92.)

As Chief Engineer of the Sanitary District, I determined the volume of flow of water through the channel, and laid out the improvement of the Chicago river, South branch and West Fork, in 1900, that is, for a flow of 8,000

cubic feet per second through the South Branch of the Chicago river, and 10,000 cubic feet through the West Fork from its junction with the South Fork of the South Branch to the northern terminus of the Drainage channel. (Vol. VI, p. 3593.)

The improvement of the channels of the South Branch and the West Fork was laid out so that the current would not be more than 1¼ miles per hour, except at bridge openings, where there was some contraction. Until 1902, as Chief Engineer, I conformed fairly well to the limitations placed upon the permit of May 8, 1899. In 1902 considerable improvements were made in Chicago river, South Branch and West Fork, to create a greater cross-section. (Vol VI, p. 3594.)

Further and later evidence relating to the works of the Sanitary District, introduced April 25 and 26, 1923, and in connection with motion of defendant filed July 12, 1920. (Rec. Vol. VIII, pp. 175-223; This Narrative, p. 339-383.)

An ordinance of the Board of Trustees of the Sanitary District of Chicago, passed and approved August 7, 1919,
201 Pearse Exhibit 1, April 25, 1923, as follows:

"An ordinance of the Board of Trustees of the Sanitary District of Chicago laying out and adopting a program for the construction and operation of works for the purification of or the removal of solids and organic and inorganic matter from sewage, trade waste, offal and other organic and inorganic matter so that within the period of the next twenty-five years not more than fifty per cent of the amount of said sewage and waste that is now passing into the Des Plaines River from the main channel of the Sanitary District will at the end of such period find its way into said river. Such works are to supplement those constructed or in process of construction for the diversion of sewage and drainage arising within the limits of the Sanitary District of Chicago.

Whereas, the Sanitary District of Chicago was organized and now exists under an Act of the General Assem-
202 bly passed on May 29, 1889, in force July 1, 1889, entitled, "An Act to Create Sanitary Districts and to Remove Obstructions in the Illinois and Des Plaines Rivers," and Acts amendatory thereof or supplementary thereto; and,

Whereas, The said Act of the General Assembly provided for the construction and operation of the Main

Channel of the Sanitary District, including adjuncts and additions thereto whereby the sewage and drainage of the City of Chicago and its environs should be diverted from Lake Michigan to the Des Plaines river, together with a certain amount of water from Lake Michigan fixed according to the population of the District as it might exist when such Main Channel should be constructed and as the population might thereafter increase, to-wit: Twenty thousand cubic feet of water per minute for each one hundred thousand of the population; and the Board of Trustees of The Sanitary District of Chicago is directed by said Act of the General Assembly to operate said works specified with such diversion of water; and,

Whereas, Said Act of the General Assembly was passed and the works provided therein to be constructed were built in order to relieve the people of Chicago and environs of a serious menace to their health and lives arising by virtue of the pollution of Lake Michigan, the only water supply of Chicago by sewage passing into same by way of the Chicago and Calumet rivers and by way of sewers debauching directly into the lake at various points along Chicago's water front; and the said works were intended also to relieve the Des Plaines and Illinois rivers of a serious condition of pollution due to a certain amount sewage and wastes of Chicago and environs passing into said river through the Illinois and Michigan Canal; and,

Whereas, The death rate per year from typhoid fever prior to the operation of the Main Channel of the Sanitary District at times equalled one hundred nintey per one hundred thousand of the population of Chicago, and its environs, which required the immediate construction and operation of works to relieve such condition; and,

Whereas, Immediately after the passage of said Act of the General Assembly of May 29, 1889, the Sanitary District was organized and thereafter commenced the construction of the Main Channel of the Sanitary District, extending from Robey street and the West Fork of the South Branch of the Chicago river to the Des Plaines river near Lockport, Illinois, a distance of thirty-two miles; and the work of constructing said Main Channel was carried forward with due speed until January 17, 1900, when the said Main Channel was placed in operation pursuant to the permit of the Governor of Illinois, in accordance with said Act, and the permit and consent of the Secretary of War of the United States; and the said

Main Channel of the Sanitary District cost the people of Chicago and its environs many million dollars; and there was required for such construction the use of all the money that could be raised by the Sanitary District for taxation and by the issuance of bonds; and,

Whereas, The Sanitary District was compelled to con-
203 struct and place in operation many adjuncts and addition to the Main Channel of the Sanitary District in order that the said Main Channel might accomplish the purpose for which it was constructed and there would thereby be constructed and placed in operation a complete and comprehensive system for a diversion of the sewage and drainage arising within the limits of the Sanitary District from Lake Michigan to the Des Plaines river; and such works included the intercepting sewers and pumping stations on the North Shore and South Shore of Chicago, the Calumet-Sag Channel, with its intercepting sewers, the enlargement of the flowage channel of the South Branch of the Chicago river and the West Fork of said South Branch, and the replacing of many old center-pier bridges with bascule bridges of modern type, and they included also many other works of similar character; and the construction of such works has largely engaged the resources of the Sanitary District, and

Whereas, the Works so constructed and placed in operation have caused a decrease in the death rate from typhoid fever per year in the City of Chicago and environs from an average rate of over seventy-five per one hundred thousand of the population for the ten years immediately preceding the opening of the drainage channel, so that now the death rate from typhoid fever is less than one-half of one per one hundred thousand of population; and,

Whereas, The Board of Trustees of the Sanitary District has recognized that by reason of various conditions existing, such as trade wastes and other materials passing into its channels and the inability to obtain at all points the necessary amount of water to dilute the sewage, thus causing local nuisances, that works should be constructed and operated to remove a material portion of organic and inorganic matter from human sewage, and also to remove and eliminate a material portion of trade wastes and other materials so that the amount of organic and inorganic matter in sewage and the amount of trade wastes and other materials passing through the Main Channel of the Sanitary District into the Des

Plaines river would be materially diminished; and The Sanitary District of Chicago has for such purposes carried on experiments and investigations to ascertain the best method to accomplish such results; and it has constructed at Morton Grove, Illinois, an Imhoff tank for the removal of a certain portion of the solids from the sewage of the Town of Morton Grove, and is constructing in connection with such Imhoff tank a sprinkling filter to further purify the sewage of said town; and the Sanitary District is constructing an activated sludge plant with necessary intercepting sewers for the collection and purification of the sewage of the Towns of Riverside, Maywood, River Forest and others, the sewage of which towns is now passing into the Des Plaines river; and the Sanitary District has authorized the condemnation of one hundred acres of land near the Calumet sewage pumping station at 125th Street and Michigan avenue, Chicago upon which site there is to be constructed an artificial sewage disposal plant for the removal of organic and inorganic matter from human sewage and wastes that
204 may pass into the Calumet intercepting sewer; and the Sanitary District of Chicago has, in the Stock Yards District, to take care of the trade wastes of Packingtown, acquired a site for purification works to be constructed thereon to remove trade wastes and organic and inorganic matters from human sewage now finding their way from that locality to the Main Channel of the Sanitary District; and the South Park Improvement Project provides for the setting aside of sufficient land for the construction of purification works for the sewage and wastes collected at 39th Street and Lake Michigan by the intercepting sewers converging at that point, which intercepting sewers serve a population of approximately five hundred thousand people, and,

Whereas, The Chief Engineer of The Sanitary District of Chicago has made investigation of the amount of trade wastes and other wastes requiring pure water to oxidize same, now being discharged through the Main Channel of the Sanitary District into the Des Plaines river, and the Chief Engineer has found and the Board of Trustees of the Sanitary District believes that the amount of such wastes is approximately equal, if it does not exceed, the amount of human sewage now passing into said Main Channel and through same to the Des Plaines river; and that there is required to oxidize said wastes and render same innocuous and nonputrescible, as much or more water from Lake Michigan than is required to oxidize and

render innocuous and nonputrescible the human sewage of the present population within the territorial limits of The Sanitary District of Chicago; and by reason of such wastes passing into said channel and thereby into the Des Plaines river, the works of the Sanitary District do not fully accomplish the purpose designed and nuisances are created at various places, which nuisances should be abated; and,

Whereas, It is the recommendation of the Chief Engineer of the Sanitary District that works should be constructed and operated to supplement the diversion works of the Sanitary District constructed or in process of construction whereby the amount of human sewage and the amount of trade wastes and other material should be continuously diminished from year to year so that at the end of a period of twenty-five years at least only one-half of the amount of sewage, including all wastes that is now passing into the Des Plaines river from the Main Channel of the Sanitary District shall enter same by way of said Main Channel; and the Board of Trustees of the Sanitary District believes that within the period of four years works of such character can be constructed and placed in operation to materially diminish the amount of such sewage and wastes passing into the said Des Plaines river, as aforesaid; now, therefore be it ordained by the Board of Trustees of the Sanitary District of Chicago:

Section 1. To supplement the works of The Sanitary District of Chicago now constructed or in the process of construction for the diversion of sewage or drainage, and to aid said works in better accomplishing the purpose for which they were constructed, the Sanitary District does hereby lay out and adopt a program for the
205 construction and operation of works for the purification of sewage or the removal of organic or inorganic matter from human sewage and the removal of trade wastes and other wastes and for the carrying on of such work at such a rate as continuously after the lapse of four years to diminish the amount of sewage including all wastes passing into the Des Plaines river by way of the Main Channel of The Sanitary District of Chicago, so that within the period of twenty-five years such purification works shall be constructed and in operation, that the amount of such raw sewage and wastes so passing into said Des Plaines River shall be at least fifty per cent less than that passing now.

Sec. 2. The Chief Engineer and the Attorney of the Sanitary District are hereby directed to take such steps

as may be necessary to carry forward the foregoing program, and the Chief Engineer is directed to report to such officers of the United States and the State of Illinois as may be interested, the progress made from time to time in carrying out said program.

Sec. 3. The foregoing preamble to this ordinance is hereby adopted and made a part of same.

Sec. 4. This ordinance shall be in full force and effect
206 from and after its passage and adoption.

An ordinance of the Board of Trustees of the Sanitary District of Chicago, passed and approved July 8, 1920, Pearse Exhibit 2, April 25, 1923, appearing as Exhibit to motion, (This Narrative P. 111).

Letter of the Division Engineer at Chicago, U. S. Army, to the Chief of Engineers, dated May 24, 1921, Pearse Exhibit 3, April 25, 1923, as follows:

"PEARSE EXHIBIT 3

May 24, 1921.

209 The Division Engineer; the Chief Engineers, U. S. Army, Washington, D. C.:

Cooperation with the Trustees of the Sanitary District of Chicago in Making a Study of Sewage Purification:

1. Referring to the letter of the Chief of Engineers dated March 25, 1920 (E. D. 28918), instructing me to cooperate with the Trustees of the Sanitary District of Chicago in making a study of sewage purification, I desire to submit the following report of progress:

2. The history of the controversy between the United States and the Sanitary District may be briefly reviewed as follows:

Under a permit issued by the Secretary of War on December 5, 1901, the Sanitary District was authorized to divert through the drainage canal a maximum of 4,167 second feet of water from Lake Michigan for sanitary purposes. Since the permit was granted the Board of Trustees of the Sanitary District has made repeated applications for permission to increase the flow, which requests have consistently been denied by the Secretary of

War on the grounds that the permit already issued is of a temporary nature only and that congressional authority is necessary for any permanent diversion. In 1907 the Board of Trustees made application for authority to construct the Calumet-Sag Channel to connect the Calumet River with the main Drainage Canal, and to draw through it 4,000 second feet in addition to the 4,167 second feet previously authorized for the Chicago River. This application was denied, and the Board of Trustees thereupon declared its intention of proceeding with the proposed work and withdrawing from Lake Michigan the additional 4,000 second feet without the sanction of the Secretary of War, unless prevented by injunction proceedings.

3. A suit was then instituted in March 1908, by the Attorney General of the United States to restrain the Sanitary District from reversing the flow of the Calumet River and from withdrawing water from Lake Michigan in any other manner and in any greater quantity than that authorized by the Secretary of War.

4. Being thus stopped by court action from proceedings with its Calumet program, the Board of Trustees in 1910 applied for authority to construct the Calumet-Sag Channel so as to carry the present flow through the two drainage canals instead of only one. In response to this application the Department on June 30, 1910, modified the existing authority so as to allow the previously
210 authorized flow of 4,167 second feet to reach the main Drainage Canal through the Calumet-Sag Channel as well as through the Chicago River, provided, however, that the total amount withdrawn through the two outlets, should not exceed the 4,167 second feet already authorized to be withdrawn through the Chicago River alone.

5. However, the Board of Trustees was not satisfied with this limitation, and in 1912 made application for authority to withdraw through the two rivers, the Chicago and Calumet, a total of 10,000 second feet. After a public hearing this application was denied by the Secretary of War on January 8, 1913. As the Board refused to accept this decision, the Attorney General filed another bill in October, 1913. This suit was combined with the one filed in 1908, but on account of the war and other reasons no decision was rendered by the court until June 19, 1920. On that date Judge Landis rendered an 'oral opinion' in which he held that the 8,500 second feet, more

or less, which the Sanitary District was now diverting from Lake Michigan, had resulted in a lowering of the lake levels, and an impairment of the navigable capacity of all of the Great Lakes except Lake Superior; and that said diversion was not necessary 'for the salvation of this community,' He directed the attorneys for the two sides to get together and prepare for his signature an order sustaining the contentions of the plaintiff, to be effective 60 days after the meeting of the Supreme Court in October.

6. Instead of that, Judge Landis, in August, 1920, in the presence of the District Attorney and myself, heard the Sanitary District Attorney, Mr. Adcock, argue that the Judge should modify his oral opinion so as to allow a total flow of 10,000 second feet. As the arguments were not finished that day the hearing was adjourned to be concluded at his summer home at Trout Lake, Mich., on some day which was to be arranged later. On account of the sickness of the Judge's brother the adjourned meeting, which had been set for the latter part of August was again postponed and has not been taken up since.

7. Ignoring all questions except that of the proper reduction and disposal of Chicago sewage, by the existing method, it is apparent, from many considerations that an excessive amount of water from Lake Michigan is not being used. Contamination of the Illinois River is proceeding rapidly down stream toward Peoria; parts of the Chicago River and its branches show a state of contamination which is all too apparent to the eye and to the nose. It is easy to believe that if, under present conditions of sewage disposal, the amount of water from Lake Michigan is suddenly curtailed, the health of Chicago might be threatened. It is apparent therefore, that if the amount of water diverted from Lake Michigan is not to increase proportionately with the increase of population in Chicago and if health conditions in Chicago are to remain normal, there must be treatment of Chicago sewage. In 1919, with these facts in mind I took up with the Trustees of the Sanitary District the question of adopting an effective program for sewage disposal. As a result, a program was adopted on August 7, 1919, which contemplated that during the following four years
211 there should be accomplished such work of land acquisition, planning, financing and actual construction as would result in a continuous reduction thereafter of the raw sewage entering the drainage canal. The program

further provided that by the expiration of twenty-five years from the date of the program the work of purification shall have been so far advanced that the amount of raw sewage entering the Drainage Canal shall equal not more than one-half of that entering now, and this reduction must occur notwithstanding the fact that at the expiration of twenty-five years the amount of raw sewage produced in the district may be almost double that now originating there. Thus by the end of the twenty-five years period the Sanitary District might be required to treat some fifty per cent more raw sewage than that now enters the Drainage Canal. The cost of carrying out this program was roughly estimated at $140,000,000.

8. The Sanitary District has had studies made by Mr. Francis C. Shenehon, a competent hydraulic engineer, for regulating and compensating works in the Niagara River and at the Galops Rapids in the St. Lawrence below the lower end of Lake Ontario. Mr. Shenehon has prepared preliminary plans and estimates for the works above mentioned. He estimates that regulating works in the Niagara River would cost approximately $1,224,000, and those at the Galops Rapids approximately $1,000,000. It is understood that the Sanitary District, if the engineering propositions of Mr. Shenehon are approved by the United States, proposes to turn over to the latter the amount required for the construction of the works above described, the maintenance and operation of the same to be at the expense of the United States. These works, it may be said, contemplate a diversion of 10,000 cubic feet per second from Lake Michigan to the Drainage Canal. Digests of these two projects as prepared for me by Mr. Shenehon at my request are as follows:

Digest of Niagara Regulation Project

The Niagara River Regulation contemplates slackwater, vessel-draft betterments in Lake Erie, the Detroit River, Lake St. Clair and St. Clair River, Lakes Michigan and Huron and St. Mary's River to the locks at Sault Ste. Marie.

The loss of draft due to a diversion of 10,000 second feet at Chicago is about 5½ inches. In a low water period such as the ten years 1893-1902, the regulation proposed will add over 14 inches to the depth of Lake Erie and Lower Detroit River; over 10 inches to Lake St. Clair,

the Upper Detroit River and the Lower St. Clair River, with proportionate increase in St. Mary's River. In a decade of more plentiful supply, the average betterment is less, because no increase in Lake stage is practicable at flood height. The regulation will compensate for lowerings due to all anticipated diversions at Chicago in the Welland and Erie Canals and in the Niagara River for power purposes, and the regulation is accomplished without danger of riparian damage from flood stages.

The excess flow of May to August inclusive is saved
212 to hold up Lake Erie level during the season of navigation. The Niagara River runs free from January to March inclusive, to avoid flood stages, to give unimpeded passage for ice and to add water for power purposes during the season of ice complications. Water power is the beneficiary of the larger winter flow, which averages 17,000 second feet in January and February, more than off-setting a diversion of 10,000 second feet at Chicago.

During the summer season about 30,000 second feet in addition to the controlled flow would be released during part of each day to furnish mill-pond water for power uses, so that the full natural river flow may pass over the cataracts to preserve scenic grandeur. Regulation of the Niagara has been delayed by the fear of the people of Buffalo that regulating works would cause ice jams and hold up the vast ice fields which cover the east end of Lake Erie. This objection is met by placing removable vessel-type gates, which are removed in January and replaced in May.

The site chosen for works is at the head of the Niagara River, opposite the old water-works at Buffalo. The River is 1,800 feet wide here with bed limestone bottom. The river channel is divided into two sluice-ways by a submerged concrete wall, three-quarters of a mile long and parallel with the current. This carries a shutter dam to complete the partition and the shutters knock down during the winter. Four gates each equipped with twelve large butterfly valves, close off the American Sluiceway. These gates rest and swing on massive concrete emplacements rising about two feet above the rock bottom. Special devices make the placing and removing of these gates easy. As each inch of added draft in Lake Erie is estimated as having a yearly value, of half a million dollars, the average increase of 13 inches is significant. The far reaching benefits, from Buffalo to Sault Ste. Marie, without works or weirs in the Detroit or St.

Clair Rivers, point this out as a project of great concern. The Niagara and St. Lawrence regulations work hand-in-hand.

Digest of St. Lawrence Regulation Project

The St. Lawrence River Regulation contemplates higher surface levels for Lake Ontario in years when the lake is naturally low, and the avoidance of high stages which might cause riparian damage. This depends on the simple principles of slack-water betterment, utilizing movable regulating gates, which when open leave the full out-flow capacity of the lake undiminished as a safeguard against flood conditions. The aim of the project is not alone to restore the loss of navigable depth due to a diversion of 10,000 second feet at Chicago (5½ inches), but to maintain the lake at the highest practicable safe stage. By the manipulation of the outflow computations show 19½ inches gain for the record low water year 1895; over 21 inches gain for the ten-year period 1893-1902; and over 12 inches betterment for the normal supply period 1907-1916.

The lower limit of slack-water betterment is at the
213 Galops Rapids below Ogdensburg, New York. Navigation betterment below these rapids is secured by impounding in Lake Ontario the excess supply of the flood months March, April, May and June, and holding this reservoired water for release in the fall months August to November, inclusive. It is found that, while Chicago takes away 10,000 second feet, this is replaced by 9,000 second feet of impounded water in September, 16,000 second feet in October and 20,000 second feet in November. The lower St. Lawrence is dependent for good volume of flow on Lake Ontario water only in these fall months. The Ottawa River entering the St. Lawrence at Montreal has a May flow of 150,000 second feet dwindling to perhaps 20,000 second feet in September, October and November.

Budgeting Lake Ontario water aids water-power by greater uniformity of flow. The attenuated January-February flow is diminished by 10,000 second feet for Chicago, and 17,000 second feet of impounded water more than restores the loss.

The two channels of the Galops Rapids are natural Sluiceways controlling the outflow of Lake Ontario. The Canadian Channel will remain unobstructed. The non-navigable American Channel, carrying 43 per cent of the

outflow, will be throttled by 1,020 feet in length of regulating works. The bottom is bed limestone, probably overlain in part of glacial drift. The works are placed at the head of this channel. The gates consist of wickets, dropped from five 200-foot span steel bridge platforms. Some increase in outflow capacity of the American Channel is recommended.

9. The special Board of Waterway from Lockport, Ill., to the Mouth of the Illinois River, etc., reported that it would require $150,000 to build works in the Niagara River and $325,000 for works in the St. Clair River to compensate in Lakes Michigan, Huron and Erie for a lowering of their levels due to the diversion of 10,000 second feet, with $15,000 annually for maintenance.

10. The Sanitary Trustees are very anxious to have a determination at this time of the amount of water the United States will permit to be diverted from the Lake. It seems to be admitted now by all concerned that this matter should be settled by Act of Congress. For example, see page 6, House Doc. 762, 63d Cong., 2d Session, from which the following is quoted:

'Further the Board believes that the total volume of water to be diverted from the natural discharge channels of the Lakes should be definitely fixed by Congress; that a project with estimate of cost for works necessary to compensate for such diversion should be prepared to the satisfaction of the Chief of Engineers and the Secretary of War; that before any diversion is made beyond that at present existing, the State of Illinois, shall transfer to the Secretary of War the funds necessary for such works as given by the approved estimate of cost; that the works shall be built by the United States with the funds so provided; and that the control and maintenance of such works shall be in and at the cost of the United States.'

11. The circumstances that the State of Illinois is now engaged in constructing a navigable link between the
214 Sanitary District Canal and the Illinois River at Utica makes it extremely desirable that an early determination be made of the amount of flow to be authorized permanently from Lake Michigan. Upon the amount of flow so authorized will depend to a large extent the character of the improvements which will be necessary to provide an 8 foot channel in the Illinois River should that depth be authorized by Congress.

12. In the letter from the Chief of Engineers dated March 25, 1920 (E. D. 28918) hereinbefore referred to, I was informed that 'at a conference with representatives of the Chicago Sewage Disposal Commission and the Sanitary District Trustee' (sic), it was agreed that the Trustees of the Drainage Canal and the Sanitary Officers of the State would make a study to ascertain what could be accomplished in regard to sewage purification before the sewage was allowed to enter the Drainage Canal or the Illinois River, and the results of such study communicated to the Chief of Engineers through the District Engineer at Chicago. In this same letter I was instructed to cooperate with the Trustees in their study of the case and to render such assistance as I was able, the study to be made 'with the idea of withdrawing the least amount of water from Lake Michigan which would be necessary for the purpose.'

13. In accordance with the instructions of the Chief of Engineers as contained in his letter of March 25, 1920 above referred to, I have held numerous conferences with the Officials of the Sanitary District with regard to their plans for sewage treatment. During the past year there has been considerable change in the official personnel of the Sanitary District, especially among those actively engaged in formulating plans for their sewage treatment system. Among those are the President Chief Engineer, General Counsel and a number of Trustees, considering these conditions the progress made has been very satisfactory.

14. In regard to the contention of the Sanitary District that it is necessary to divert more than 4,167 cubic feet per second in order to avoid contamination of the City water supply and consequent epidemics, I was empowered in a memorandum of the Secretary of War for the Chief Engineers dated July 21, 1920 to say 'that if Judge Landis' decree is accepted as final, the War Department will issue no permit, since it is without legal power to do so, but will ask no further orders from the Court to enforce the limitation so long as the City of Chicago proceeds with dispatch to prepare plans and put them into process of execution for its sewage system. If the City of Chicago then prepares plans and consents to the War Department having current knowledge of its activity, either by reports to the courts or otherwise, the situation will be under the control of Judge Landis until the whole problem is disposed of. If however, the City

of Chicago proposes to appeal the case and takes no steps pending the appeal to cure the trouble, Colonel Judson should be instructed to make no concessions or promises of any kind.' This memorandum of the Secretary of War was obtained through the Chief of Engineers at my solicitation for use whenever Judge Landis
215 decides to finish the hearing on Attorney Adcock's arguments for allowing a total diversion of 10,000 second feet. In this connection Mr. Adcock was making the argument that the War Department would be arbitrary in acting on the findings of the court, and a statement was desired which would show that the Secretary of War would not be arbitrary in the matter.

15. On January 17, 1921, a formal conference was held betwen Mr. Chas. F. Clyne, United States Attorney, and myself representing the United States and the Trustees of the Sanitary District, their attorneys, Consulting Engineer and Chief Engineer. At this conference attention was invited to the Memorandum of the Secretary of War for the Chief of Engineers dated July 21, 1920, above referred to, copies of which were furnished the Attornevs for the Sanitary District. The Trustees agreed to take under advisement the proposition of the Secretary of War as set forth in his memorandum and to submit an answer thereto at a later date. At this conference an agreement was reached with the Sanitary District authorities that I be furnished with an outline of their present plans for sewage treatment. A copy of the memorandum furnished in accordance with the above agreement giving an outline of the work already completed, that now under way and proposed, and indicating the probable future policy of the Trustees, is enclosed herewith.

16. A second conference was held on February 7, 1921, at which the United States Attorney was represented by his assistant Mr. J. B. Boddie. The proposal of the Secretary of War as embraced in the last paragraph of his memorandum of July 21, 1920 (E. D. 98093/657), was discussed and the Sanitary Trustees stated that they were unable to accept the proposition that Judge Landis' decree be accepted as final. On the other hand they stated that they would proceed diligently in the preparation and execution of plans for the treatment of sewage within the Sanitary District. They stated that since the conference of January 17, 1921, they had prepared their budget and in it had placed some $8,000,000 for sewage treatment operations, and that in subsequent budgets

they would continue to provide for work upon a large scale to carry into effect plans already prepared or now being prepared for sewage treatment. They estimated that depending upon conditions in the labor and material market the entire cost of such treatment would be in excess of $100,000,000 and perhaps as much as $140,000,000 but stated that they were confident that they could provide this sum so that in somewhat less than 25 years they would be able to at least carry out the program adopted August 7, 1919, and perhaps do even better than was proposed in that program.

17. It was understood that the matter before Judge Landis would be proceeded with regardless of the more or less futile negotiations that have been in progress with reference to the proposition of the Secretary of War that the decree of Judge Landis be accepted as final. Mr. Boddie stated that he understood the situation and understood it to be the duty of the United States Attorney's office to proceed with efforts on its part to secure
216 the formulation and entering of the formal decree by Judge Landis, opposing any efforts of the Sanitary District to procure a modification of the decree. It may of course be regarded as a fact that the Sanitary Trustees will appeal from the decree of Judge Landis if it is entered without modification, satisfactory to them.

18. The Chief Engineer of the Sanitary District, at the conference of February 7, 1921, informed me that it was the intention of a committee of Trustees and employes ofthe Sanitary District, including himself, to visit Fort Worth and Houston, Texas, and other localities, at an early date, to inspect activated sludge plants in course of construction or operation and suggested that I accompany them. This I subsequently undertook to do but my travels were interrupted by illness.

19. While the Sanitary District doubtless has authority under existing state laws to proceed with its sewage treatment program, in an excess of caution it has caused bills to be introduced in the State Legislature for explicit authority to construct the proposed sewage treatment works, in accordance with the accompanying memorandum, and the controlling works in the Niagara and St. Lawrence Rivers as well, in accordance with the projects of Mr. Francis C. Shenehon, hereinbefore referred to. These bills are still pending with good prospects that they will be passed.

Opposing interests are also endeavoring to secure legislation to limit the bonding power of the Sanitary District, by requiring that each bond issue be subject to a referendum.

20. In the meantime the Sanitary Trustees are proceeding energetically with their plans for sewage treatment and disposal as outlined in enclosed memorandum. Since the date of their report they have acquired 180 acres of land located on the North Shore Channel as a site for their proposed North Side purification plant.

21. The progress made by the Sanitary District is well illustrated by Exhibits E and F constituting part of enclosure showing their budget appropriation for 1921 and their expenditures during the ten year period 1910-1920. During the last named period the expenditure for sewage treatment works has amounted to approximately $9,400,000. Their budget for 1921 provides $6,500,800 for the completion of old projects and $3,242,500 for new projects.

22. The program of the Sanitary District, if carried out, will insure the practicability of keeping the volume of water diverted from Lake Michigan within limits which it is hoped all concerned will finally deem reasonable.

W. V. Judson, Colonel, Corps of Engineers, Divn. Engr., N. W. Divn. 1 encl."

Langdon Pearse, a witness for the defendant, testified as follows (April 25 and 26, 1923; Rec. Vol. VIII, pp. 176-197): 177 Resides Winnetka, Illinois.

Been employed with The Sanitary District of Chicago in various capacities since March 1st, 1909; at present in the position of Sanitary Engineer, in charge of the sanitary engineering work of the District.

Graduate of Harvard College with the degree of A. B. 1899; and from the Massachusetts Institute of Technology, with a degree of Bachelor of Science in Civil Engineering; also Master of Science in Civil Engineering, of date 1902.

In the period between 1901 and 1909, at which time became connected with the Sanitary District, was successively Level-

man for the Massachusetts Harbor and Land Commission, on the Brockton Ship Canal; Assistant Engineer to the Charles River Dam Commission, under John R. Freeman; Assistant Engineer for the Commission on Additional Water Supply in New York City, known as the Herring-Burr-Freeman Commission; also as Personal Assistant to George C. Whipple in work for the Augusta Water District, Me., Cleveland and Jersey City; and also in connection with the suit of *Missouri* v. *Illinois*.

From there, was Assistant Engineer for the Improved Water and Sewage Works at Columbus, Ohio, involving the construction of a water filtration and softening plant; also sewage treatment; and also Assistant Engineer on the Greater Water Supply for the People's Water Company of Oakland, California, a water filtration project.

From 1909 to date, have been successively assistant engineer, division engineer, and since 1917, sanitary engineer with the Sanitary District of Chicago, in charge of all sanitary work, involving the laboratory work covering chemistry and bacteriology, in connection with our testing stations, studies of the Canal and River, as well as industrial wastes; the construction and operation of four Testing stations, respectively on domestic sewage at 39th Street and the Lake, packinghouse waste, tannery sewage and Corn Products sewage; the design and construction of intercepting sewers in size from six inches to twenty-two feet in diameter, including the North Shore Intercepting Sewer, the Stockyards Intercepting Sewer, the Calumet Intercepting Sewer, and the 52d Avenue Sewer Outlet; the design of sewage pumping stations, known as the Evanston, Des Plaines, Calumet, 95th street stations, and also the remodeling of Lawrence Avenue and 39th Street; the design of sewage treatment works and other construction at Morton Grove, the so-called Calumet works at 125th Street and Cottage Grove Avenue, the Des Plaines River Treatment Works, near the Subway Hospital in Broadview; Glenview Sewage Treatment Works, and the designs for the North Side Sewage Treatment Works.

Have further been in charge of the general operation of the Sewage Treatment Works, of which we now have three in operation, one at Morton Grove, one at Calumet, and one known as the Des Plaines River.

178 In addition to these technical duties, have also been in charge of preparing special reports and data for the use of the Chief Engineer and others in different suits.

In addition to duties with The Sanitary District, have further served as a Consultant for the U. S. Public Health Service on stream pollution for the last three years; and in that connection served for the Sanitary District on a joint survey with the U. S. Public Health Service of the Illinois River, extending over a period of one year.

In private capacity as a Consulting Engineer, have executed the following works, in special partnership with George W. Fuller; designed and built the Evanston Water Filtration plant. As a member of the firm of Pearse, Greeley & Hansen, we designed and built the Decatur, Illinois Dam & Sewage Treatment Works; the Whiting, Indiana Water Filtration plant, and the Winnetka, Illinois, Water Filtration plant.

And further, as engineer, have made reports for, designed and built works forthe Sanitary District of Decatur, the North Shore Sanitary District, the Downers Grove Sanitary District, the Sanitary District of Champaign and Urbana; and in addition have made miscellaneous reports on industrial wastes for the Holland-St. Louis Sugar Company, the Standard Oil Company of Indiana and others.

Am a member of the American Society of Civil Engineers, and the American Institute of Consulting Engineers.

Witness further testified:

I was first employed in 1909, with the intent of making a complete and thorough investigation of the sewage treatment problem of The Sanitary District. I have been at that ever since.

I first went into the engineering details in the so-called 1911 report of Mr. Wisner, who was then Chief Engineer; and later in 1912 and 1914, I went into the matter again in connection with this particular lawsuit for Mr. Wisner. And further in 1919 and 1920, in connection with the report of the so-called Expert Commission composed of Eddy, Fuller and Hatton.

It was early evident that to unravel the sewage treatment problem, a close study was required, not only of the sewage from the human sources, but also of the wastes of industrial origin.

The study of the domestic sewage was begun by a testing station at 39th Street and the Lake, operating on sewage coming from an area of over twenty-two square miles, and from a population of 270,000 and up. This was very free from industrial wastes. In this Station were tried all the practical methods of sewage treatment then known, including septic tanks, Imhoff tanks, biolytic tanks, sprinkling filters, etc.

The difference between the different tanks mentioned is essentially one of construction as well as operation. By
179 septic tanks, I mean the single story tank in which the solids deposited from the sewage are allowed to accumulate, with cleaning at infrequent intervals.

By the Imhoff tank, I mean a double deck type of tank in which the upper chamber serves as a settling chamber, the solids passing through a trap into the lower chamber where they digest at leisure, the gases passing off through a separate vent, in order not to contaminate the sewage flowing through, which is settling.

The sludge from this tank may be drawn at intervals of two weeks, in the warm weather; the storage capacity provided being from four to six months, according to the design.

The biolytic tank is a special device, in which all the sewage entering the tank comes in at the bottom and passes through the sludge deposit. This tank has been used only experi-

mentally, and while it gave a remarkable reduction of sludge, it produced offensive odors and was therefore discontinued.

The sprinkling filters mentioned are beds of crushed stone, in the experimental work ranging from five to ten feet in depth, but usually in active work around six feet and a half, the stone being composed of one and a half to two inches in size. These beds are placed upon prepared underdrains to permit free drainage of the liquid trickling down through. The liquid is sprinkled upon the surface by nozzles spaced up 13½ feet on centers, operating intermittently and dosing the beds at a rate of from two to five million gallons per acre per twenty-four hours.

The 39th Street Testing Station was operated from October, 1909, to January, 1915. The results that were obtained there indicated that with the more dilute sewage found in Chicago, liberal provision for treatment, loadings, was required.

The value of the Imhoff tanks and sprinkling filters was clearly demonstrated.

Following the study of the domestic sewage, we entered upon an extended study of the Packingtown situation in January, 1911. The preliminary investigation showed the lack of knowledge for handling such waste. Consequently a Testing Station was established in 1912, and operated until September, 1918. These studies showed that the activated sludge process was the most promising of success on Packinghouse waste.

I might explain that the activated sludge process is a process in which the solids settling from the sewage are held back and conditioned by the blowing of air, so that in a period of about two weeks it has acquired the property of changing from the organic matter coming in the sewage to a more mineral form. It is essentially a biological process, involving the same principles as in the sprinkling filter, except that the films which are active and doing the work are held in suspension by air blown in at the bottom of the tanks, in

stead of the films being around the periphery of the stones in a bed above ground. The sludge is retained by settling tanks, returned to the incoming sewage and then held in contact and in thorough mixture by the air blown in 180 at the bottom of the tanks.

From day to day a certain amount of sludge can be removed from the system, about one thousand pounds per million gallons of domestic sewage, and in the case of Packingtown about between three and four thousand pounds of dry solids per million gallons.

This sludge is higher in nitrogen than the usual sludge from Imhoff tanks or other processes.

In connection with our packinghouse investigation, a thorough inspection was made of every packinghouse in the Sanitary District, the flow from each being gaged and analyzed before entering the sewer.

In 1911, all the packinghouses were examined. In 1917, the work was repeated, the flow of thirty-one houses being measured and analyzed in a period of about three months.

The study of the tannery situation was begun in 1912. A recent investigation showed twenty houses all located on the north branch of the Chicago River. After a number of inspections, a tannery testing station was established in December, 1919, and operated up to December 31, 1922. In this the various processes applicable to handling tannery wastes were tried, including sprinkling filters and activated sludge. A survey of the industry was also made, house by house.

The Corn Products Refining Company plant at Argo was early recognized as an outstanding source of organic pollution. After some preliminary work, a testing station was established in 1921, by which the experiments have been conducted to date, using activated sludge and also a sprinkling filter. The flow of the plant has been measured, analyzed and correlated to the grind. This plant manufactures primarily starch and glucose, and is the largest of its kind in

the world, grinding upwards of 75,000 bushels of corn every twenty-four hours.

There are other sources of pollution, which we have investigated in a cursory way, which add to the load, but are not so important as those listed. Among these may be mentioned the Pope Beet Sugar factory, miscellaneous butterine factories, paint and glue works, gas works, paper mills and wire mills.

The study I have made in the last fourteen years has led me to divide the Sanitary District into five main geographical projects, namely:

The Calumet, south of 87th street.

The Southwest, south of the canal and the river and north of 87th street.

The West, north of the canal and river, and south of Ful-
181 lerton avenue in general, and the

North Side Project, north of Fullerton avenue.

In addition, there is the Des Plaines River Project.

Besides these five main projects, there are the Packingtown, Corn Products and Tannery Industrial Projects. The first two require separate treatment plants distinct from the human sewage plants, whereas the tannery situation is to be combined with the North and West Side Projects.

Besides the major projects outlined, there are and will be for many years small treatment units, plants for isolated villages such as Morton Grove, Glenview, Shermerville and the like, where the population is small and the distances are too great to warrant the construction of an intercepting sewer at present.

I have made a careful study of the population in the Sanitary District from the United States census figures from the component parts of the census of 1890, 1900, 1910 and 1920. From the figures an estimate has been made of the future population of the District up to 1960. The growth of the various sewage treatment project areas has also been worked out in detail.

We have plotted the populations as they have existed, with the correction for the date, on paper, and then projected a curve on that.

We have further tested the ten-year increment by the actual differences, taking into account the growth of the territory of the Sanitary District, and have arrived at the figures given in the table.

This method has been used and is one that is usual among engineers.

Pearse Exhibit 4 as follows:

The Sanitary District of Chicago

217 Population and Area

Year	Population	Area	Date of census
1890	1,149,758	185.0	June 1
1900	1,775,882	185.0	June 1
1910	2,311,810	358.1	Apr. 15
1919	2,940,906*	388.14*	.....
1920	2,986,000	395.51	Jan. 1
1921	3,071,000	.....	.....
1922	3,142,000	437.39	.....

* In June, prior to annexation of Salt Creek Villages.

181 Table for the years 1920, 1930, 1940, 1945, 1950, 1955 and 1960, as Pearse Exhibit 5, April 25, 1923, is as follows:

The Sanitary District of Chicago

217 Population in Various Sewerage Districts

Locations	1920	1930	1940	1950	1960
North Side Treatment Plant	590,000	800,000	1,615,000	1,230,000	1,450,000
West Middle Plant Incl. Loop	1,300,000	1,420,000	1,550,000	1,680,000	1,800,000
S. W. Treatment	850,000	1,040,000	1,230,000	1,415,000	1,600,000
Calumet	160,000	225,000	290,000	350,000	415,000
Miscellaneous	100,000	215,000	340,000	465,000	595,000
S. D. C. Total	3,000,000	3,710,000	4,425,000	5,140,000	5,860,000

Dec. 31, 1921.

182 These loads are shown in the table which I have prepared based on the census populations nad the projected population for the human load, and based upon our surveys for the industrial load expressed in equivalent population.

Table shown as Pearse Exhibit 6 as follows:

The Sanitary District of Chicago

217 Population Estimates

Year	Human	Industrial equivalent	Total
1920	3,000,000†	1,500,000	4,500,000
1930	3,710,000	1,700,000	5,410,000
1940	4,425,000	1,900,000	6,325,000
1945	4,782,000	2,000,000	6,782,000
1950	5,140,000	2,100,000	7,240,000
1955	5,500,000	2,200,000	7,700,000
1960	5,860,000	2,300,000	8,160,000

† Based on 1920 Census.

182 The estimates for the years following 1930, and up are given in the Exhibit 6, following the figures given for 1920, for the totals there expressed.

The method by which I have arrived at the population equivalent of the industrial wastes is based on the dissolved oxygen required to oxidize the putrescible matter in sewage. Continued research over many years in the laboratory of the Sanitary District has shown this to be a reliable and accurate measure of the strength of sewage, inasmuch as it utilizes exactly the same biological activities which are effective in the stream. By stream I mean the Canal, Des Plaines and Illinois Rivers.

Essentially, the test depends on mixing with the sample sufficient standard water saturated with dissolved oxygen to supply enough dissolved oxygen to oxidize the organic or putrescible material, in five, ten or twenty days, as the case may be, and leave a small amount of oxygen over at the end of a period.

The amount of dissolved oxygen required is expressed in parts per million. For purposes of comparison, a ten-day period has been chosen in our work, inasmuch as 90 per cent of the oxidation of the putrescible material is generally completed in sewage within that period. Such a test is called the Biochemical oxygen demand, and has been widely used by the U. S. Public Health Service, the Sanitary District and other research workers, as being more delicate and expressive than the old line chemical determinations. In some instances we have used nitrate of soda, added in known amounts, in place of dissolved oxygen.

The first step in the study of our sewage was to determine the amount of dissolved oxygen required per capita to oxidize the putrescible matter in human sewage. Prior to the work of the Sanitary District this figure had never been determined. Experiments were made on the sewage at 39th 183 Street Pumping Station during the year 1914. This sewage was chosen because a thorough inspection of the area tributary showed no industrial wastes likely to upset the tests.

On 179 days, hourly portions were collected during the twenty-four hours and daily composites were made. These were analyzed. The flow of the sewage was measured. The population tributary was estimated. From the data the average figure was determined that 100 grams of oxygen are required per capita to properly oxidize the human sewage, or 0.22 pounds. Subsequently other research chemists confirmed this figure to me personally.

The next step was to determine the amount of putrescible material requiring oxidation from the different industries. This was done from time to time as follows:

The Packingtown and Union Stock Yards situation was investigated in the summer of 1917 between July 9 and October 6. At that time thirty firms were actively engaged in the packing and allied industries, in addition to the Stockyards. All of these houses were examined, and the flow gaged

and analyzed from forty-one outlets, besides the public sewers, and certain outlets from the Stockyards. In all cases (except three of the smaller houses where the examination lasted two days) the sampling and gaging continued a week, night as well as day.

The flow was read as frequently as every ten minutes in most cases. For analysis, individual portions were taken every ten minutes and combined into hourly composites, which in turn were combined into day or night composites, weighted according to the flow. I mentioned the fact we made day and night composites, bacause there was a marked difference in the flow, in the strength day and night, as well as in the quantity.

From the determination of the biological oxygen demand and the flow, the total oxygen requirement was calculated. Based on the 0.22 pound per capita, the effect of the Stockyards and Packingtown was found to be practically 1,000,000 people. This investigation alone cost $5,661.97, an amount which was reimbursed to the Sanitary District by the packers.

For the Tannery industry, the investigations made between 1911 and 1919, gave a rough indication of the equivalent. However, the most detailed survey was made in the summer of 1921, when twenty tanning houses were inspected. For each house, the flow was gaged and analyzed, the work being done substantially in the same manner as for the Packing-house survey. The determination of the biological oxygen demand and the flow from the houses showed a total oxygen requirement equivalent to 70,000 people, on a normal hides capacity rating. In addition, seven wool pulleries and three wool scouring houses were examined.

For the Corn Products Refining Company, the investigations were made in December, 1921, and January and February, 1922, in connection with the testing station then operated on the Corn Products wastes. The flow was gaged and sampled throughout the twenty-four hours, analyses being made on twenty-four composites. The resulting oxygen

demand showed that the population equivalent was 411,000 people, at that time when a grind of 64,500 bushels was being made. Since that time the grind has increased.

The Sanitary District Channel in the main section was designed upon the assumption that the runoff of the Chicago River would not exceed 10,000 cubic feet per second, and could therefore be diverted from the lake by a channel having that hydraulic capacity.

If the diversion from the lake is limited to 4,167 cubic feet per second, the likelihood of overflow into the lake is very much increased, with a result that pollution of the water supply is likely to occur, which will be severe. This is due to the fact that the intercepting sewers as designed cannot be made large enough to carry more than twice the dry flow in 1950; hence overflows will come into service, at times of storm, spilling sewage into the branches of the Chicago River. Consequently, with any reversal of the flow, storm water and sewage mixed will fill the river and be swept into the lake.

It does not seem safe to me to rely entirely upon chlorination of the water supply for protection, where water would be exposed to sudden and so-called explosive pollution. In my experience, the only adequate and certain protection would be filtration, accompanied by chlorination, as a finishing process.

I have prepared an estimate of the use of water at the present time in the City of Chicago, that is as of 1920; and also for 1945 and 1955. These estimates have been checked with those of the Water Bureau of the City of Chicago, and are in substantial agreement. That is practically the pumping. That has nothing to do with the diversion from the lake by the Sanitary District.

Table of water consumption for 1920, 1945 and 1955,
218 Pearse Exhibit 7, April 25, 1923, is as follows:

Year	Population	Mil. gal. per 24 hr.	Gal. per cap. per 24 hr.	Max. Rate mil. gal. per 24 hr.
1920	2,700,190	715	265	945
1945	3,919,275	1,355	346	1,800
1955	4,406,909	1,610	365	2,130

185 I have made a rough estimate of the cost of filtration, basing the capacity of the plant on the maximum daily rate, and including in round figures the low lift pumping stations.

In 1945, the cost would be for construction approximately $90,000,000, or by 1955, a cost of $106,500,000. These costs are in round figures and undoubtedly would require some additional expansions to increase the figures in a detailed survey, because of the necessity of the connections to the intake tunnels and other incidental work, which at present it is difficult to estimate. I present them as an indication of figures based on the cost of works in the past and present, to show the magnitude of the filtration expenditure.

The estimate may be within fifteen or twenty per cent, based on round figures, calculated per million gallons for plants of like nature. They are figures that perhaps are not accurate enough to predicate a bond issue upon for a public vote, but are accurate enough to indicate the magnitude of the expenditure for handling the filtration of a city of the size of Chicago. Such a plant would be the largest filtration plant of its kind in the world, and would necessitate special designs and lay-out, so that the figures necessarily at the present moment are not contractors' estimates of what the work could actually be built for, but they are what we call preliminary estimates which may be accurate within fifteen or twenty per cent, thereabouts.

I believe that in 1945, the cost of maintaining and operating such filter plants for the city would exceed three million

dollars, and that by 1955, the cost would have probably reached $3,526,000, the additional cost being due to the additional service required for the population, and increased pumpage.

To these figures necessarily should be added interest charges and depreciation, to give the total annual costs. These costs cover labor, chemicals, supplies and general repairs necessary and incidental to the operation of such filtration plants.

I have made a calculation based on the plan outlined by the ordinance of August 7, 1919, the so-called "Colonel Judson plan." This was designed to outline the program for the Sanitary District for the twenty-five years following 1920, to construct works which would reduce the load on the channel to one-half that existing in 1920. The figures are 186 presented as follows:

For Conditions in 1920.

By census, S. D. C. in 1920	2,986,000
Estimated Industrial Wastes	1,500,000
Total	4,486,000
One-half	2,243,000

Equivalent population expressed in the equivalent sewage from human beings. That is, that represents, according to such estimates, half the waste passing from the southern terminus of the Main Channel of the Desplaines River. The figure of 2,243,000 is in round figures to the nearest thousand.

The equivalent population, under the Colonel Judson plan that would be required to reduce the sewage pollution to in 1945, outlined in 1945, the conditions are as follows:

For Conditions in 1945.

Estimated S. D. C. in 1945	4,782,000
Estimated Industrial Wastes	2,000,000
Total	6,872,000
Deduct residual one-half	2,243,000
Requiring treatment by	4,539,000

Four million five hundred thirty-nine thousand is the population which I understand would have to be provided for by treatment works, under this so-called Colonel Judson plan.

That is, during the period from 1920 to 1945. I have based the figures on the minimum legal dilution expressed in the Act of the Sanitary District, namely 3⅓ cubic feet per second per thousand population, and on that base I find the population of 2,243,000 requires 7,500 cubic feet per second, in round figures for dilution. From the sewers there may come a flow which we have assumed to be 346 gallons per capita per twenty-four hours for a population of 4,782,000 in 1945, which would give a flow of 2,482 cubic feet per second, making a total flow through the channel of diversion from the lake, and of water supply coming through the sewers of practically 10,000 second feet; a difference of only a few unit second feet, so that it rounds out to the 10,000 second feet.

187 On the assumed basis of the minimum legal dilution 4,617 cubic feet per second, at 3½ cubic feet per second per thousand population, is equivalent to 1,250,000 people. In 1945, the total population equivalent, both human and industrial is estimated at 6,782,000. The difference, or 5,532,000 people would require treatment. In 1945, this means 993,000 more people than would be required under the Colonel Judson plan.

188 It would take, probably, to build these additional works for the 993,000 people not over ten years. The human population would amount to 5,500,000 in 1955 and the industrial wastes 2,200,000, making a total of 7,700,000. The figures given previously may be developed as follows: The total population in 1955 we have estimated at 7,700,000; the total population in 1945, at 6,782,000, making a difference of 918,000 population, as the growth in the ten years.

If you take the total in 1955, namely 7,700,000 and from this deduct the population equivalent to the 4,167 cubic feet per second, namely 1,250,000, you have as a difference as of 1955 a population of 6,450,000.

Under the Colonel Judson plan as mentioned before, the population requiring treatment in 1955 would be 5,457,000, the difference then between the two being 993,000 people.

We have made an estimate of the cost. The sewage treatment program based on this plan (August 7, 1919 ordinance) was estimated in 1920, to require directly an expenditure for sewage treatment of $104,335,000, out of a total program of over $106,000,000. I say over $106,000,000 because in addition to the $104,000,000 would be the other items such as regulating works, bridges over the Main Channel, and dredging of the Calumet River, which amount to $7,250,000. Of the 189 total as estimated, over $9,490,000 has been spent or put under contract to date, thus leaving a total of about $94,845,000 still to be expended. The amount of approximately $9,000,000 has been either expended or contracted for since 1920.

Estimated cost of sewage treatment projects and necessary construction work 1922-1945, as Pearse Exhibit 1, April 26. 1923, is as follows:

The Sanitary District of Chicago

Estimated Costs of Sewage Treatment Projects and Necessary Construction Work for Period 1922-1945

Work under contract and completed project	Contract liability	Date of completion
Calumet Treatment Plant	$2,200,000	1922
218 " Mach. & Adm. Bldg.	520,000	1923
" Sewers—Contract #10	130,000	1922
" " " #11	2,300,000	1923
Desplaines Treatment Plant	300,000	1922
Oak Park Sewer	500,000	1922
39th St. Conduit Extension	2,000,000	1924
Calumet-Sag Channel	200,000	1922
North Side Sewers—Contract #1	1,610,000	1923

Proposed wokr	Estimated cost	
Calumet Sewers—Contract#1	400,000	1923
Harbor Ave. Sewer	250,000	1924
Extension Blue Island Sewer	425,000	1928
Sewer to Riverdale & Dolton	200,000	1928
Sewer—Burnham, Hegewisch & W. Hammond	500,000	1928
95th St. Pumping Station	1,000,000	1924
Calumet Sag Channel	120,000	1923
Dredging Calumet River	1,000,000	1929
Glenview Treatment Plant	25,000	1922
La Grange Sewer & Treatment Plant	75,000	1923
Oak Forest Sewer	300,000	1923
Extension Desplaines Plant	100,000	1924
California Ave. Bridge	750,000	1924
Elmwood Park Sewer	250,000	1925
Stockyards Treat. Plant (Demonstration)	350,000	1926
" Sewers, Pump. Sta. & Screens	1,000,000	1926
Cicero Ave. Bridge	1,500,000	1926
Remodel Lawrence Ave. Pump Sta.	200,000	1926
219 Broadview Sewers	200,000	1926
Corn Products Treatment Plant..	1,500,000	1927
Regulation Works—Niagara & St. Lawrence	2,500,000	1927
North Side Treatment Plant	13,500,000	1928
" " Sewers (exc. Cont. #1)..	7,800,000	1928
Crawford Ave. Bridge	1,500,000	1928
Harlem Ave. Bridge	1,000,000	1929
Calumet Sp. Filters & Plant	2,000,000	1930
Extention North Side Plant	2,000,000	1931
Stockyards Treatment Plant	6,000,000	1932
Remodeling 39th St. & 73rd St. Pumping Sta.	900,000	1934
West Side Sewers	13,300,000	1940
" " Treat. Plant (Imhoff)	10,900,000	1940
South West Side Sewers	9,400,000	1945
" " " Treat. Plant (Imhoff)	7,200,000	1945
*Misc. Treat. Plants & Sewers	11,200,000	1927-1945

We based this schedule on the following assumptions as to the progress that might be made. I would make this explan a-

tion, however, that this general program was worked up in 1922, that is not 1923, and we estimated then that the North Side work would be started in 1922. The plans were practically ready last fall for the first contract of that plant, but owing to the discussion with Evanston over the location of
the site, the work has not actually been put under con-
190 tract, but the program is outlined to start on the North
side plant in 1922, and completed by 1928.

The District has acquired approximately 200 acres at Oakton avenue and the North Shore Channel for the purpose of a site. This site was acquired about two years ago. Last year, when it was announced that we were prepared to start work on the plant, objections were raised by various Evanstonians, and only to-day a large delegation was in the office before a public hearing of the Trustees, protesting against the use of that site, and alleging possible damage to the property values in Evanston.

The Trustees have indicated as yet no decision in the matter, but have been investigating very seriously the entire question since last October. The change in the board in December re-aligned some of the committees. We expect a decision shortly, and orders to proceed in one way or another on actual construction. The reason for the objection is that Evanston has expressed a desire to annex 2,500 acres west of the Channel, extending out towards the north branch of the Chicago River north of Oakton avenue; and the claim is made that the location of this plant will injure the desirability of that locality for the best class of residential buildings.

I would add this, however, that on this north side project we have already built five miles of sewer from Sheridan Road south to Oakton avenue, so that the northwest line of the intercepting sewer is completed and ready to hook into the pumping station. And we have completed preliminary plans for the work from the south, and have already started on the plans for re-modeling Lawrence avenue, so that the sewage that now passes to the river through the Lawrence avenue

conduit from the Lincoln Park region will be diverted to our interceptor.

The suggestions of Evanston are that we can move the plant five miles or more to the West, which would increase the sewer cost of the project at least a million and a quarter a mile for about four miles anyway, as a minimum. That is five million dollars and this would probably add to the operating expenses approximately $100,000 a year. I have been informed that that land is worth about $1,000 an acre. Our board paid $1,500 an acre for the site of the treatment plant.

In our schedule, we further assume that the Corn Products plant could be started in 1925, and completed in 1927. I purposely allowed three years there for legal conditions, to arrive at an agreement with the Corn Products, because in our experience with the packers, after we had outlined the engineering plans for doing the work, that overcame the engineering objections, we have been approximately four years negotiating as to the legal difficulties; and negotiating to arrive at an agreement under which the work could be prosecuted.

191

For the Stock Yards project, we allowed for a start in 1925, and assumed it would be completed in 1932. In making this allowance, we assumed that legal negotiations would take at least two years; that the design of the sewers and works would be done by 1924, and the construction of the sewers, pumping station, screens, and the first unit of aeration tanks completed in 1926. A year is allowed for the design and contract plans for the entire plant, and a year for necessary legal negotiations. The plant is assumed to go under construction in 1929, and to be completed in 1932.

I would explain this arrangement was made, because when Mr. W. B. Richardson, representing the packers, and myself representing the District brought in a report outlining the engineering method of proceeding, in 1917, we made a recommendation that the work be done by gradual steps, first to construct the sewer, pumping stations and screens for the entire

works. Mr. Richardson differed with me and said we ought to have the screens only for one unit, that is about one thirtieth of the entire flow, and then we both agreed that the activated sludge plant recommended by both of us as to process should be built gradually, in order to demonstrate to the packers on a working scale of at least a million and a half gallons per day, the entire feasibility of the process.

Since that time, I have taken the position that the size of the plant to start might be markedly larger, as we know more of the process to-day, and have been operating a plant at Maywood for over eight months.

The sewage is much stronger at the Stock Yarks, expressed in biological oxygen demand. The sewage in the Stock Yards will run from 500 to 1,000 parts per million, as against 125 to 150, not over 200 in Maywood.

The amount of suspended matter in the Stock Yards will run from 3,000 to 4,000 pounds of dry matter to the million gallons, whereas at Maywood we have 1,000 pounds. In other words, there is three to four times as much solid to be handled.

Further, with the screens at the Stock Yards, we estimate we can take out about 1,000 pounds of dry material to the million gallons, whereas at Maywood we are only taking out 200 pounds a day for 3,000 gallons. That is sixty pounds of wet material with eighty per cent moisture, or sixteen pounds of dry material to the million gallons.

The Stock Yards sewage is one of the strongest sewages in the United States produced on such a scale, and is full of fresh organic mattter, blood, particles of meat, hay straw, and undigested contents of cattle paunches, hogs and other animals.

192 I feel that a reasonable program for handling has been devised, namely to de-water the sludge, which in its original form contains about ninety-nine per cent of water; reduce that to eighty per cent or less by filter process, with the addition of either an acid or a coagulen like sulphate of alumina

and then take the solids with less than eighty per cent of moisture and dry them in a rotary heat drier. They will then be in a form containing ten per cent of moisture, capable of passing through an eight mesh sieve, and suitable for sale in the market as fertilizer. We have been offered by at least two responsible firms the amount of five dollars and ten dollars per ton f. o. b. cars for Chicago for such material, to be used in mixing fertilizer for the Southern market, or for truck farm either in the East or the Ohio Valley.

That has been worked out in the last two years. In addition, the City of Houston has been selling similar material for eight dollars a ton for use in the cotton belt in the South, prepared in much the way that I have indicated. The City of Milwaukee is installing a plant now to handle the sludge in exactly this fashion.

In order to build up a sufficient treatment to meet the requirements of the Colonel Judson program, or a more elaborate program, we have had to plan the construction of the so-called West Side Project, including the sewers, and a plant which, for the purposes of this estimate, we have assumed would be a settling plant to remove all the solids which may settle in the Channel. The construction of this plant has been assumed to begin in 1932 and to be completed in 1940.

Further, for the South West Side, we have laid out a similar program for treatment, including intercepting sewers and a settling plant, the construction to start in 1935 and to be completed in 1945.

Besides the new work which I have mentioned, viz: the North Side, West side and South West Projects, the extension of existing projects will require attention in the life of the program.

The Desplaines River sewage treatment works, which has been in operation since August 1, 1922, will need extensions in 1924, to take care of the increased population.

The Calument treatment works, which has been in operation since October, 1922, will need an extension of the tanks, and

we have assumed an addition of sprinkling filters to produce a higher grade effluent than we were supplying, in the year 1930. We have further allowed for the extension of the North Side treatment works, assuming that they were completed in 1928, in the year 1931.

As originally outlined the program covers an equivalent population of 4,251,000 taking the Imhoff tank treatment
193 as the equivalent of one-third complete treatment. This is within five per cent of the figure set for 1945, as outlined by the Colonel Judson plan. This method of handling was assumed by settling the sewage which was not given complete treatment, in order to retain all the settling solids.

I would explain that the reason for presentmg the material in this shape is, we have to construct certain intercepting sewers to take out the sewage and carry it to certain designated points for treatment. Having done so, those sewers serve for a certain population, and we have taken the tributary populations and added them together in order to supply a project that would come approximately to the population set by the plan. In order to bring it exactly to the plan, we would have to provide a little additional treatment, as I remember, because I think the figure of 4,251,000 is a little lower than the amount called for, which would of course increase the expense of the construction.

I did not endeavor to bring it out exactly by taking the per capita figures and equating them by slide rule, but have left them in this shape to show exactly the projects that would be developed, and what they would accomplish.

If the flow were cut to 4,167 c. f. s., it would be necessary, we believe, by 1945, that the West Side plant, instead of being constructed with settling tanks would be equipped for complete treatment, probably by activated sludge. We would still leave the South West plant as a settling plant. Such a program would provide in the year 1945, for the population equivalent of 5,328,000, which comes within four per cent of the figures set.

The same explanation would apply here as made, namely that in order to come out exactly to the population set by the population computations, sufficient additional treatment would have to be provided on one plant by sprinkling filters or other means, to bring up the total, which can be done, but would increase the amounts of the estimates.

The additional construction cost necessitated by the cut in diversion would exceed $16,800,000 if carried out by 1945. I have my doubts whether this could be done at the rate of progress that is necessitated by the methods of administration in our work and the financing, judging by past experience.

I have therefore estimated that in order to finance the work, cover the legal requirements and the like, somewhat more time would be required than on the previous work, which has been taken to be a period of ten years. In the interval from 1945 to 1955, in which the extent of that cut would be made, working on our assumptions, there would have to be expended not only the sum of $16,800,000 as noted, but a further sum roughly estimated at $16,710,000, making a total of $33,510,000, to cover the growth in population, which would have to be treated, as well as the difference required on account of the lowered diversion.

194 In addition to these figures, the filtration of the water supply of the City of Chicago would be required, so that as of the year 1955, there would be added $106,500,000 to the program requiring financing.

The true cost of the additional population is not shown by our method of computation outlined, because the method of assembling by districts indicates a comparative cost for handling the sewage with a reduced diversion, which is lower than it really is, if you take the per capita costs and multiply by the population. That comes in the method of assembling the projects and calculating the cost of intercepting sewers in this treatment.

I have estimated the cost of the activated sludge plants with intercepting sewers as $25 per capita, with an annual cost of around $2.25 to $2.75 according to the method of handling the sludge. I am therefore conservative in saying the cost in round figures on account of this cut in diversion would add to the sewage treatment program approximately $25,000,000 based on the actual per capita charges for construction, and $2,250,000 for annual costs.

If the diversion was cut to 4,167 cubic feet per second, I believe that there will be ultimately a heavy burden placed upon the cities and industries located on the Illinois River, particularly in the metropolitan area around Peoria and Pekin. While in 1920, the census population was only 88,207 for the two cities, there was in addition a starch works at Pekin grinding about 25,000 bushels of corn a day, equivalent to 158,000 people, besides other Corn Products industries about which little data could be obtained.

This equivalent population, through growth of industry as well as of population, I have estimated might exceed half a million in 1930. With the continued growth up to 1945, during low water, treatment may become necessary, making an additional burden upon the inhabitants of the State of Illinois. In 1920, the urban population on the banks of the
195 Illinois River from Joliet to the mouth totaled 200,472.

Table of expenditures for sewage treatment since 1909 for construction purposes, Pearse Exhibit 2, April 26, 1923, is as follows:

Expenditures for Sewage Treatment since 1909 for Construction Purposes

219

Year	Total
1910	$ 157,816
1	.....
2	55,269
3	19,683
4	490,468
5	280,348
6	700,648
7	1,533,260
8	1,543,227
9	1,803,064
1920	2,835,387
1	5,052,511
2	6,691,982
	$21,163,663

195 Table of expenditures for sites for sewage treatment works up to 1921, Pearse Exhibit 3, April 26, 1923, is as follows:

PEARSE EXHIBIT 3—Apr. 26/23

The Sanitary District of Chicago

Expenditures for Sites for Sewage Treatment Works Up to 1921

219

Treatment plant	Amount paid for site	When acquired
Calumet Pumping Station	$ 12,423.40	May 27, 1915
Calumet Treatment Plant	159,636.00	Feb. 13, 1920
Desplaines Treatment Plant	25,194.00	Oct. 4, 1917
52nd Ave. Treatment Plant	39,505.88	Mar. 31, 1913
Evanston Pumping Station	11,341.60	April 20, 1916
North Side Treatment	269,995.00	April 21, 1921

195 This table was made in the same way, from the records of the District, checking the amounts against the vouchers paid, and the dates against the orders of the Board printed in our proceedings.

Since 1909, up to the end of 1922, there has been expended under my direction by our engineering and laboratory forces the sum of $97,842, for construction and equipment on sewage testing work.

In addition to this sum, we have spent in the maintenance and operation of the works, including the operating of our laboratories and the other expenses chargeable to the investigations, the sum of $563,815. This makes a total expenditure on our books for construction, equipment, maintenance and operation of $661,657.

When I first came with the District in 1909, the art of sewage treatment was less understood on a large scale than now. There was a transition period in the art; the old septic tank was in disfavor, as originally installed at Columbus. Experiments were found to be necessary, and were devised by men of the standing of Mr. Rudolph Hering, and others who studied the problems of the District, and had been connected with it since its inception in 1889.

We found the sewages we had to meet were so varied in strength and behavior that tests were needed to define the 196 most efficient method of treatment. Tests were needed in order to find how much sewage could be treated with a given area of plant; for instance in sprinkling filters, how many hours were required for the settling of the sewage in settling tanks.

We saw very clearly that the problem ahead of the District in 1909, was a gigantic one, involving the largest sewage treatment works in the world, and involving the necessity of producing a high grade effluent for a large part of the sewage of the District.

In addition, we had to confront not only the human problem but the industrial waste problem of enormous extent, and at

that time no solution was known for its treatment. Neither was the amount of the waste known. The period required for preliminary investigation was indefinite, but we knew that we had to study the sewage, not alone as to methods of treatment, but also to improve the methods of analysis.

The method I have explained of determining the oxygen consumption was one of our changes in method which has enabled us to express population equivalents. Short time tests we knew were of little value. Our experience had shown that at least a test running over the four seasons of the year was required, because the operation of a sewage plant is different in the winter from the summer; and usually at the end of the year we had found improvements or changes in the studies that led us to continue.

Aside from the tests, surveys were required of the District. Preliminary plans had to be made; sites had to be secured, and then legal obstacles had to be overcome.

Our lawyers finally determined that the Act had to be amended, which was done in the last session of the Legislature, over two years ago now, whereby we were given the explicit right and command to build sewage treatment works, whereas prior to that time, I was informed that our right to establish complete works was in doubt and open to contest.

The opinions, I think during Mr. Adcock's incumbency as attorney, and prior to that time, were that whatever we did was merely an incident, and there might be a doubt if we had to condemn a site as to whether our powers would be seriously questioned, because we were acting more or less under implied powers, instead of actual, explicit powers.

I regard the population figures as presented as very fair. They are calculated from census figures, which are as close as we can auctually get them. We have had the advantage of the actual enumeration districts of the census. In representing the actual loadings on the Main Channel, we believe they may prove low rather than high, because of the fact we
197 have made no allowance in the figures for the floating population in Chicago, and in particular for the Loop Dis-

trict. In 1920, this was estimated at 250,000 people. Of these 250,000, some are commuters from within the boundary of the district, but many undoubtedly come from the outside, according to our figures.

The hotels and clubs we think may house 100,000 people The increase in floating population we have determined to be approximately 50,000 for every decade, so that we believe by 1945, that there is an effect from the floating population which might be between 375,000 and 475,000, for which we have made no allowance in these estimates.

We have also made no allowance for any factor of safety, to take care of the variations due to the variations in industry, or to extremely hot weather, which you may get in the summer time, that would upset our allowance of the effect of the water taken from the Lake, or for other contingencies.

Neither have we allowed for any extension of the boundaries of the district, which I believe will undoubtedly occur, as shown by our past experience. All these factors would tend to increase the expenditures for sewage treatment.

I think the estimates of costs of construction are conservative. We based them on unit prices slightly lower than have prevailed in the last two years. The office experience in the Sanitary District during the last two years, and in fact since the beginning of the war, has indicated that the contractors that we have to deal with want more for doing the work than we as engineers generally estimate. I think in our experience in the last two years, if I am not mistaken in my recollection, we have in general received figures that are higher than the estimates we have made as engineers, along the lines indicated in my evidence.

I have further assumed that the general conditions of labor, and of the material market, will continue. I have not attempted to estimate the possible changes that may occur in the stretch of twenty-five years.

Table of expenditures for construction of sewage treatment works 1910-1922, as Pearse Exhibt 4, April 26, 1923, page opposite.

Henry M. Christie, witness for the defendant, testified as
198 **follows** (April 26, 1923; Rec. Vol. VIII, pp. 198-201):

Resides at Chicago; employ of Sanitary District since 1892, except during the years 1901-1902 and 1909 to 1910; familiar with the accounts; compiled a table showing present and future resources of the District by way of bond issue, tax income showing annual expectations in income from those sources, consolidated with certain estimates of the Sanitary District Engineers as to construction program; table covers years 1922 to 1945, inclusive. The table known as Christie Exhibit 1, April 26, 1923, page opposite.

Column 1 shows the years; column 2 shows the population increment as based on rates of increase shown by the last
199 decennial period; column 3 shows estimated valuation, assessed valuation as taken from information obtained from the Assessor's Office of Cook County, the increases being based on past experience; column 4 shows the assessed valuation per capita; column 5 shows future tax rate as taken uniformly at 0.40 of 1 per cent, this being assumed as the limit which the Sanitary District is likely to realize under the present conditions; column 6 shows the taxes for any one year, based on the assessed valuation of the preceding year; column 7 shows future bond issues to provide revenue; column 8 shows total gross revenue and is the sum of the figures
201 in columns 6 and 7; column 9 shows the amounts required each year to liquidate the present outstanding bonds; these are for old bonds that have been issued for prior work; column 10 shows the amounts required each year to pay the interest on the present outstanding bonds; column 11 shows the amount required each year to redeem future bond issues. The bonds are figured for redemption at the rate of five per

CHRISTIE EXHIBIT 4, April 26, 1923.

Summary of Statement of Resources and Expenditures of the Sanitary District of Chicago under 1922-1945 Construction Program.

Based Upon Plants Going into Operation as follows, viz:

Desplaines	1923
Calumet	1923
Corn Products	1927
North Side	1928
Stock Yards	1932
West Side	1940
South West Side	1945

Resources:		
Taxes—Net	$211,850,000	
Sale of Bonds—Net	60,949,000	
		$272,799,000
Contra:		
New Construction	$106,300,000	
Ad. Maintenance & Operation	106,400,000	
Interest on Bonds	59,768,880	
Surplus	330,120	
		$272,799,000

Note—Bonds outstanding Jan. 2, 1946 ..... $84,050,000
Maximum bonding capacity Jan. 2, 1946 99,000,000

The Sanitary District of Chicago

Expenditures for Construction of Sewage Treatment Works 1910-1922

	1910	1911	1912	1913	1914	1915	1916	1917	1918	1919	1920	1921	1922	Total

cent per annum; column 12 shows the interest on outstanding bonds; column 13 shows the estimated cost of administration and running expenses of maintenance and operation of the works of the Sanitary District, based on the experience of recent years; column 14 is the total; column 15 is the net revenue. Christie Exhibit 4, opposite.

Tests made by the Sanitary District to determine length of time required to change flow in channel from 4,167 seconds feet to 10,000 seconds feet.

George M. Wisner, witness for defendant, his qualifications being heretofore shown (This Narrative, p. 177; April 15, 1914, Rec. Vol. VI, pp. 3404-3405), testifying in sur-rebuttal said:

Since testifying previously, I have had two different tests made, one on February 22 and the other on March 8, 1914, to determine how much the discharge in the main channel and the Chicago River would change when the discharge at the Controlling Works was increased from approximately 4,000 cubic feet per second to 10,000 cubic feet per second.

3405 For the 12 hours preceding the time at which the flow was changed from approximately 4,000 cubic feet to 10,000 cubic feet per second, we tried to adjust the flow of the canal so as to have as near as possible a uniform flow of 4,000 cubic feet through the channel.

3406 On February 22, and 23, from six P. M. until about 5:30 A. M., we flowed as near as it was possible 10,000 cubic feet through the Controlling Works and measured the water, as I stated, at the other places by means of current meters. The gaged were also read.

The flow was increased at about 5:53 to about 6:10; took that long to increase the flow, manipulate the works; that is P. M. on February 22. Generally, I would say throughout

that time the flow according to the power house measurements probably averaged 200 cubic feet over 10,000.

The computations were worked up of the discharge at Lemont and at Summit and Dearborn Street.

The section at Summit was about four or five miles above Willow Springs. The discharge measurement at Lemont was taken by means of a Haskell Current Meter; at Summit we used the Price Meter; and at Dearborn Street a Haskell Meter. We only had those three meters available at that time.

I would have run this test longer but it was absolutely impossible to do it without absolutely breaking a lot of contracts that we had for the furnishing of power, and I could not run it at that time any longer than the 12 hours approximately, as testified to.

The largest flow that we were able to get at Lemont was 9300 cubic feet per second, within the whole time between six o'clock P. M. of February 22, and 5:30 of the next morning.

There is a peculiar thing that seems to happen when this flow is turned on: There will be an indication of a large flow at Lemont about an hour and a half to an hour and 50 minutes after the flow was increased at Lockport.

It is eight miles from the old Controlling Works in round figures, and ten miles from the power house. That flow
3407 only keeps up for a very short time, and it drops off as though there were possibly an influence, an impulse set up in the water; and the water only being measured at one particular point, I am of the opinion you get a false indication of the discharge at that time, because the flow then did not go up again until about 3:30 the next morning.

That was an hour and a half afterwards. Then it dropped off to about 8200 cubic feet per second.

It reached that at ten o'clock at night, when it raised gradually to 9300 and some odd cubic feet per second at 3:30 the following morning. That is we had 9300 flow twice, about 7:30. About an hour and a half after we started to turn it

on at about 5:50. Then it went down to about 8,000 cubic feet per second between 9:30 and 10 o'clock that night. Then gradually rose to 9300 feet at about 3:30 the following morning.

At Summit, the first indication of the increase in the discharge came at seven o'clock, and it gradually rose so that at eight o'clock there was a flow of 7,000 cubic feet. There was a gradual rise of the discharge at Summit then until
3408 about one thirty, when the flow reached 8200 cubic feet. From then until the end of the test, at about six o'clock the next morning, the flow ran practically 8,000 cubic feet. It is about four or five miles above Willow Springs; that is about 12 or 13 miles above Lemont. 22 miles from the power house.

The measurements at Dearborn Street were carried on, as I stated, by a Haskell Meter and the flow had an increase, starting in about 8:30 that night, began to slowly increase and raised gradually to about 2:30 in the morning when there was a flow of about 5800 cubic feet per second.

It then gradually decreased to five o'clock in the morning when there was an indicated flow of 5500 cubic feet per second; and from five o'clock in the morning until six in the morning it increased, so that at that time there was approximately 6200 cubic feet per second passing Dearborn Street.

I would say in this connection that Dearborn Street being so close to the lake, it is influenced by the rise and fall of the lake.

The height of Lake Michigan generally varied during February 22d and 23d, at the time of the tests, from plus .5 up to plus .9, in round numbers; but the elevation of the lake
3409 varied two or three-tenths within half an hour, at times.

We made another measurement on March 8, as stated before. I did this to have a check upon the first one; and tried to make it under a little better conditions; used more current meters, more discharge sections. It was a more complete

test, and ran over a longer period. The weather conditions were better.

Prior to increasing the flow, we tried to get as near uniform flow at about 4,000 cubic feet per second as was possible. We started in on that day early in the morning of March 8 flowing 4,000 cubic feet per second.

That was changed so that we seemed to have a fairly even flow there for some distance above the Controlling
3410 Works; and the flow was increased at 12 o'clock noon to 10,000 cubic feet per second. We maintained the flow at 4,000 cubic feet per second from about three or four in the morning until twelve noon of March 8. Of course it took some time to get the rest of the channel flowing that amount. For instance, around the different gaging stations the flow seemed to vary between four and five thousand cubic feet per second, at the different sections, at twelve noon, when we changed the flow.

The flow was put on at about 11:50 in the morning and at 12:00 noon, or shortly after that, there was 10,000 going through the Controlling Works and power house at Lockport; and the flow as indicated there got up as high as 10,500; but it ran at 10,000 or above until one A. M. of the following day.

There were discharge sections at Dearborn Street, Loomis Street, Robey Street, Willow Spring, Lemont and at Lockport; the Lockport discharge section being about a half a mile this side, or towards Chicago, from the old Controlling Works in the Rock Section.

From Lockport up—first was the Controlling Works and then the Lockport discharge section; Lemont, Willow Springs, Robey Street, which is the junction of the Chicago River and the Canal; Loomis Street, Dearborn Street.

3411 From the Power House to Lockport, 2.46 miles; to Lemont from the the same place (I will give the distances every time from the Power House) 9.51 miles; Willow Springs, 16.93 miles; Summit 22.30 miles; Robey street, 29.90

miles; Loomis street, 31.0 miles; Dearborn Street, 35.2 miles: Lake Michigan, 36.3.

The flow at the Controlling Works averaged 10,000 cubic feet per second from 12:00 o'clock noon until 2:45 the next morning, a time interval of 14 hours and 45 minutes.

The flow at the Lockport discharge section was approximately 4,000 cubic feet per second when we started, and the indicated flow was 8,000 at about half past twelve, or half an hour later. At 1:50 to 2:00 o'clock, the flow at this station reached a little over 8900 cubic feet per second, and it ran approximately at that flow until 5:30 P. M. of March 8. It then increased to 10,000, which it reached at 7:00 P. M. of March 8.

The flow at this discharge section then varied from 10,000 to 10,400, and down to 9500 at 3:30 A. M. of March 9. That is the Lockport discharge.

They were run continuously from about 10:00 A. M. of March 8, until 9:30 to 10:00 A. M. the next day, with the exception of the Dearborn Street Section, which was dis-
3412 continued at 12:00 o'clock midnight on account of an accident to the meter; and also at Lemont. At those two places we had no record from 12:00 o'clock midnight, or 12 hours after the test started.

The next station is Lemont; and the flow at Lemont at about 12:00 o'clock varied between 4500 cubic feet per second and 5,000.

That is 12:00 o'clock noon of March 8. It gradually rose, so that at one o'clock, or one hour after the flow was increased, there was a flow of approximately 8500 cubic feet per second.

It increased uniformly from one o'clock to approximately two o'clock. In connection with the Lemont station, it did not start to increase until 12:20. At 2:00 o'clock it reached 9100 cubic feet, when it seemed to vary from a little above 9,000 to a little below 9,000, from 2:00 P. M. until 6:00 P. M. when there was a fairly uniform increase to 8:00 P. M., when the flow was 9600 cubic feet. It ran fairly uniform at this

same discharge until about 9:30, and from 9:30 it increased uniformly to 10:00, when there was an indicated discharge at Lemont of 10,000 cubic feet per second. And it continued at approximately that discharge until 12:00 o'clock, when the meter, as I said, was damaged; got out of order.

It was ten hours after the water was increased from 4,000 to 10,000, before we got a discharge of 10,000 cubic feet at Lemont.

At Willow Springs, the flow started to increase at about 12:45 P. M. From that time, it uniformly increased until 1:10 or 1:15 when the flow was 7,000 cubic feet per second. From this time until 4:00 P. M. the flow uniformly increased so that the discharge at Willow Springs was 7800 cubic feet per second. It ran practically at the same discharge until 6:10 P. M. when there was a discharge, of 8,000 cubic feet per second. From 6:10 it increased uniformly until 9:30 P. M. when the discharge was 9,000 cubic feet per second. From 9:30, the increase was uniform to 3:50, when the highest discharge was reached, amounting to 9300 cubic feet per second. That is 3:50 the morning of March 9. From then on the water dropped slightly until 6:10 or 6:20, when there was a flow of 9,000 cubic feet per second. After that the discharge commenced to decrease as the water had been lessened at Lockport.

3413

The next station where a discharge measurement was made was Robey street. The flow started to increase at 1:35 or 1:40, and at that time the indicated flow at Robey street was about 4,600 cubic feet per second. That was at 1:35 when it started to increase, and it increased uniformly to 2:20 when the flow was 5,900. From that time to 4:40 P. M., the flow as indicated was practically constant. There was a uniform increase from 4:40 to 5:40, the flow increasing to 6,500. From this time, that is, from 5:40 P. M. to 12:00 o'clock midnight, the flow increased fairly uniformly and the discharge was 7,800 cubic feet. It ran fairly constant from this time to 4:00 A. M., the discharge varying between 7,800

and 7,900 cubic feet. Beginning at 4:00 A. M. the flow gradually increased so that at 6:40 to 6:50 it ran a maximum of 8,400 cubic feet per second. From that point the discharge decreased. The change had been made at Lockport before that.

The next gaging was at Loomis street. At the beginning of the test, the flow at Loomis street as indicated by the meter was about 3,800 cubic feet. The first indication of an increase of flow, that was at all marked, was at 2:00 P. M. From 2:00 P. M. until 3:20, there was a uniform increase and the flow was 5,100. From this time to 12:30 A .M. of March 9, the flow increased fairly uniformly and there was a discharge of 7,000 cubic feet per second.

From 1:20 until 4:00 o'clock in the morning, the meter was out of service and was being repaired, and the record on that section was incomplete during that stretch; but at 4:20 the flow was 7,000 cubic feet per second and increased gradually to a maximum of 7,200 cubic feet per second at 8:30 A. M., when the flow started to decrease.

In regard to Dearborn street, I wish it understood that this section and the discharge is affected by the lake which is only a mile away from it. The discharge at the beginning of the test, as indicated by the discharge measurement at this place was about 4,200 cubic feet per second. The

3414 first marked indication of a change in the discharge started at 4:00 o'clock P. M. of March 8, when it uniformly increased, or practically uniformly increased, to the end of the test at 12:00 o'clock midnight, when the discharge amounted to 7,300 cubic feet per second.

As stated before, the meter became damaged at that time, or out of order, and no further measurements were made at that section. The flow at 4:00 P. M. at Dearborn street was 4,350 cubic feet per second.

3415 I doubt if you could get more than 9/10ths of the total change in less than from twenty-two to twenty-four hours at Robey street when the channel flow at Lockport has been increased from 4,100 to 10,000.

We made a study as to how long it would take storm water coming from the Chicago River basin to concentrate in the Chicago River in cases of storm, by the gaging of several of the large sewerage districts, in which the sewage has been measured, and we have made a study of the time after the rain starts until the maximum discharge was reached. This study has been very careful and has been carried on in the 39th Street District, and Robey Street District and the Diversey avenue sewerage district. These are three separate and distinct areas about Chicago; one of them being on the South side, another on the West side and another on the North side.

3417 These measurements were authorized by the Board of Trustees upon my recommendation, and have been carried on under my direction, and the results have been worked up under my direction. That is the Chief Engineer was directed by a resolution or ordinance of the Board of Trustees to make these measurements to install weirs and measure certain discharges from certain well defined sewerage districts.

3418 From these studies as near as we can determine, the time of concentration of the storm run-off on the large sewerage areas upon the urban drainage area of the City of Chicago will be from three to three and one-half hours. The suburban district along the North Branch North of Lawrence avenue would take in the neighborhood of twenty-four hours to reach the maximum. The discharge of 10,000 cubic feet per second will occur, in heavy storm, in the neighborhood of three to four hours. I mean there would be that amount of water coming into the Chicago River South of Lawrence avenue.

It would not be possible to so manipulate the Controlling Works at Lockport as to change the flow from 4167 to 10,000 cubic feet per second so as to prevent any of the storm water or sewage of the City of Chicago going into Lake Michigan.

3419 The engineer or executive in charge of this work of changing the flow from 4,167 cubic feet per second to

10,000 cubic feet would have to anticipate every storm by at least from twenty to twenty-one hours in order to prevent the Chicago River from discharging partly into the lake. This means that every time there was the slightest indication that there might be a rainstorm, the flow would have to be increased so that if a heavy storm did occur, the Chicago River would not be reversed and discharged into Lake Michigan.

Another point is that it would be impossible to maintain a channel from Lake Michigan to Lockport that would ordinarily flow 4,167 cubic feet per second and still be capable of flowing 10,000 cubic feet per second when needed.

For the reason that with such slow velocity as would obtain with a flow of only 4,167 cubic feet per second the channel would fill with sediment coming either from the solids of sewage and street washings or from the sediment in the lake water itself. The result would be that during the slow flow the channel would be gradually filling up with sediment so that at the time you needed a larger flow there would not be a sufficient cross sectional area to permit the flow of
3421 10,000 cubic feet per second through the canal.

COST OF NAVIGATION FEATURES OF THE MAIN CHANNEL OF APPELLANT.

John R. Freeman, testified as follows (Rec. Vol. III, 1176):

It is certain beyond all doubt or serious question that a channel over substantially the same route could have been built of sufficient capacity to carry 10,000 second feet or 14,000 second feet, which is the utmost that it is proposed to ever divert through this canal, for only a fraction of the cost that was necessitated in building a channel of the present dimensions, in order to fit it for navigation. Had the channel been built solely for sanitary purposes, that is, solely so as to give it a capacity to convey from 5,000 to 10,000 or 14,000
1177 second feet of water at the lowest levels to Lake Michi-

gan, a cut probably less than ¼ part of the width of the present cut would have served every purpose, for carrying 5,000 second feet considering that the slope of this channel from the Chicago River to Lockport could have been made at the steep rate of more than 1 foot per mile, and thus give a high velocity to the current.

It is certain that a much narrower channel than the present would have easily carried from 10,000 to 14,000 cubic feet of water per second, and that the amount of excavation would have been correspondingly reduced.

Although I have not had time to design such a channel, and compute its cost, it is my belief from general experience in the construction of large aqueducts and canals, that careful estimates would show that more than fifteen million dollars of the expenditure actually made upon the Chicago Sanitary and Ship Canal was distinctly for the benefit of navigation at some future time. And it is my belief that at some future time, whenever the contemplated works are completed through to the Mississippi River, this extra width and capacity obtained as a result of this expenditure will far outweigh any possible injury to navigation arising upon the Great Lakes or through connecting channels, from the lowering of their levels to the extent which has been estimated.

Appellee offered in evidence a memorandum from Major Ferguson to the Secretary of War, dated November 4, 1913, concerning the intervention of the United States in a certain suit pending in the Illinois courts. This memorandum reviewed the history of The Illinois & Michigan Canal and among other things states, Rec. Vol. IV 3888, 3891, as follows:

The object, authority, and responsibility of the United States is to secure a suitable waterway from Lake Michigan to the Mississippi River. By direct appropriations such a waterway has been or is being provided for portions of the route. For the section of the route from the Illinois River

to Lake Michigan, U. S. Congress attempted to reserve the right of way in 1822. By default of Illinois this attempt became void. In 1827 Congress provided for this section by the indirect means of land grant to Illinois.

* * *

It is therefore assumed that the effect of the United States appearing in this case will be to establish (1st) the contention that there is a contract between Illinois and the United States, and (2d) the nature of this contract, whether it is (a) a narrow contract requiring specific fulfillment by enlarging this canal, or (b) a broad contract to provide a suitable waterway from Lake Michigan to the Illinois River. If the ruling be that the contract is a narrow one (a), it is believed that any attempt to enforce it will be, in fact, futile. The required dimensions of the canal are nowhere specified and it would seem that these dimensions must hereafter be determined, as they have been heretofore by Illinois. If the ruling be that a broad contract exists, the obligation resting on Illinois will not be lessened, but may be met by (1) specific fulfillment—enlarging old canal—or (2) otherwise providing a waterway, and such a ruling by her Supreme Court should have the effect of causing Illinois to decide promptly how this acknowledged obligation would be met. Illinois' self-inflicted paralysis in this case is perhaps more technical than it is intentional. She has the undoubted right to maintain this canal or not, according to her judgment on costs and benefits, but in case she refuses to maintain it, its forfeiture should be considered.

Conditions of Chicago River (April 15, 1914) compared with time prior to Sanitary District improvements.

Mr. Wisner further testified and Exhibits 7, 8, 9, 10 and 11, here shown, were offered. (Opposite this page.)

The depth of the South Branch of the Chicago River before the Sanitary District started work was approximately sixteen to seventeen feet. It is now twenty-six feet except at

a few bridge openings; that is the South Branch of the Chicago River.

3422 The central 100 feet of the stream is twenty-six feet in depth with a depth of sixteen feet at the Dock lines.

Exhibits 7, 8, 9, 10 and 11 above shown are maps of the Chicago River from Lake Michigan through the main branch of the river, and South and West on the South Branch of the Chicago River to Ashland avenue, which is about half a mile east of the beginning of the canal. The maps are drawn accurately to a scale of 200 feet to the inch and indicate the dock lines of the river, the bridges, and indicate the condition both before and after the improvement.

3423 With the exception that it does not show the location of the old bridge piers and center pier protections of the bridges that were removed and changed from the swing type of bridge to the center pier—to the bascule type of bridges. It does indicate the type of bridge, and when it is completed, as stated on the map, for instance State Street Bridge, which was built by the Sanitary District is a Scherzer bascule, as indicated, "built by the S. D. of C." meaning Sanitary District of Chicago, completed 1903. So by looking at these maps at the different bridges, you can learn by whom they were built and when completed.

The lake is on the right hand side of the map, Wisners Exhibit 7. When I say on the right hand side of the map, I mean to have it so placed that the words "Chicago River" in the part tinted blue reads right side up; that being to the East, and Lake Street being to the West.

The streets like 5th Avenue, LaSalle, Clark, State, run practically north and south, and streets like Kinzie and Lake run east and west. This first sheet shows the junction of the south and the north branches of the river.

On Exhibit 7, which is as I stated the main branch of the river, the improvements made by the Sanitary District consisted of the removal of the State and the Dearborn Street bridges, which bridges were of the center pier swing type such

as now exists at Fifth Avenue and Michigan avenue. These were replaced by the bascule type of bridge giving a wide center opening and doing away with the center pier and the center pier protection, which clogged up the river and interfered with navigation. The Sanitary District also dredged the river in the vicinity of these bridges to a depth of twenty-one feet.

On the main river, in addition to what was done by the Sanitary District, the City of Chicago removed the LaSalle Street tunnel, deepening the river at that place. The tunnel at LaSalle street interfered with navigation; the boats at times being stuck on it and blocking the river.

Wisner's Exhibit 8 of this date consists of a map of the same scale extending south from Lake street to 12th street showing the docks on the river before and after improvements made by the Sanitary District. This stretch of the river has been widened practically throughout its entire length, the widening being indicated by the dark blue tint. By applying a scale to this dark blue tinted area, the amount of the widening can be determined at any place. Generally, it varies in width from nothing to approximately ninety feet. The 3424 part tinted green of which there are two places indicated on this sheet are stretches along the river which have not as yet been widened for the reason that the property has not been acquired by the Sanitary District, but is included in the general project, and it is expected will be obtained and widened within the next year.

There are condemnation suits pending against both of these pieces of property, referring to the parts tinted green, one being on the east side of the river between Van Buren street and Harrison street and labeled "Union Elevated R. R. Co. Power House."

That is called the Union Loop Power House. The other is indicated by "Tract Number 201," the 201 being in a circle and being just north of Taylor street.

The Sanitary District has widened and excavated the river throughout this stretch to twenty-six feet in depth; has re-

moved all of that part tinted a dark blue thus widening the river, and has rebuilt all the docks where the river was widened.

The width where completed is at least 200 feet.

All except those two that have not yet been excavated. The District has removed a center pier bridge and built a bascule bridge at Randolph street, which was completed in 1903.

The Washington Street Bridge and the tunnel thereunder were removed by the City of Chicago and a new bridge completed in 1913 at this street.

The Madison Street bridge, the one that now exists, is of the center pier swing type, and is to be removed by the city of Chicago.

It has been ordered out and plans and specifications are being prepared and it will be rebuilt within the very near future.

The Jackson Boulevard Bridge is now being removed by the Sanitary District, and is to be replaced by a bridge
3425 of the bascule type, having a wide opening.

The opening of the Jackson Boulevard Bridge will be 167 feet in width; the one at Madison street, as I recall, is to be 180 feet, somewhere in that neighborhood.

The bridge openings there are only about fifty-five to sixty feet in width at the present time. At Jackson Boulevard, the opening is a little wider, I believe about ninety feet.

The next bridge to the south is the Metropolitan Elevated Railroad Company Bridge. This was ordered out by the Secretary of War.

It is part of the contemplated plan of the Sanitary District to remove and replace the Van Buren Street Bridge with a bridge having a 200-foot opening.

The Harrison Street Bridge, which was of the center pier type has been removed and rebuilt by the Sanitary District, being completed in 1905.

Polk Street Bridge which was of a similar character has been removed and was rebuilt by the City of Chicago, being completed in 1910.

Taylor Street Bridge which was of the center pier type was removed by the Sanitary District and rebuilt in 1900.

The railroad bridge just south of that and indicated as "B. & O. C. T. R. R." was of the center pier type and was built by the Sanitary District, being completed in 1901.

Twelfth Street Bridge has been ordered out by the Secretary of War and is to be rebuilt jointly by the City of Chicago and the Sanitary District, with an opening of 200 feet instead of the present opening of about fifty-five to sixty feet.

Wisner Exhibit No. 9, is the third sheet of this set, being of the same scale, and is a map of the south branch from 12th street to 18th street inclusive. The part tinted a dark blue represents the river widening performed by the Sanitary District, and the part tinted green is a piece of property not yet obtained, but which is under condemnation; and in my opinion will be obtained within the next few months, when this whole stretch of the river will have been completed; so that from Lake street to the beginning of the
3426 Drainage Canal, with the exception of the three pieces mentioned and the stretch of the river at the Metropolitan Elevated, the entire river has been widened to at least 200 feet and even to twenty-six feet or more, with the exception of the bridge openings of the old center pier bridges.

The widening on this stretch of the river varies from zero to eighty feet in width. The river was redocked and deepened as stated.

The bridge marked "St. Charles Air Line" which is practically on 16th street, is to be rebuilt by the railroad companies. Plans are now being prepared, and this bridge is to be taken out and replaced with a 200-foot opening bridge.

The 18th Street Bridge which was of center pier type was rebuilt and replaced with a bascule type bridge completed in 1905 by the Sanitary District.

Wisner's Exhibit 10 of this date is a continuation of this map and gives the Chicago River on the same scale, 200 feet to the inch from 18th street to Halsted street. The same general tinting indicates what has been done by the Sanitary District. The widening varies from nothing to nearly 140 feet in width at Collision Bend.

It got its name on account of there being so many collisions at this place before this widening was made; I mean collisions between vessels.

The original width at the Bend was a little over 100 feet. There was a narrow point on the river immediately south, or west of 18th street, and at that place the Sanitary District widened it about 120 feet at the widest point. The old 18th Street Bridge, on account of the narrow river and bend in it, the vessels were unable to use but one bridge opening, that one being on the east side of the river. By that I mean vessels of any size.

The bridge marked "P. Ft. W. & C. R. R." is a bridge owned by the Pennsylvania Railroad Company, and is now in the process of being removed; a new bridge having been built at this place with I think a 200-foot opening.

The Canal Street Birdge was built by the Sanitary District and completed in 1903. That was not of the center pier type, but was of a narrow opening type, known as a jackknife. It stood askew and was a very difficult place for navigation.

The 26th Street Bridge was of the center pier type and was removed; rebuilt by the Sanitary District; completed in 1906.

The next sheet shows in the same way the improvements made by the Sanitary District from Halsted street to Ashland avenue. The part near Ashland avenue tinted brown is a turning basin that was built by the United States Gov-

ernment to facilitate the turning around of vessels after
3427 going up the river. Generally, this river was widened throughout this stretch, throughout the entire length, to give a channel which is now at least 200 feet wide and twenty-six feet deep.

The Sanitary District removed a center pier bridge and rebuilt with a bascule bridge at Main or Throop street, completing it in 1903. And one at Loomis or Deering street, completing that in 1904; and one at Ashland avenue, completing that in 1903.

The river from Ashland avenue down the West Fork to the beginning of the Canal was over 200 feet in width, and was simply deepened by the Sanitary District to twenty-six feet in depth.

At the lower end of this last sheet the water as indicated on the left hand side of the sheet is the West Fork of the South Branch, from which the Canal starts at Robey street.

The indicated water to the right of the map is the South Fork of the South Branch, the far end of which is known as Bubbly Creek, being located near the Stock Yards, and having been mentioned in this case several times.

The middle water stretch is the entrance to the old Illinois and Michigan Canal.

On Wisner's Exhibit No. 8, I neglected to mention that the City of Chicago had removed and rebuilt a tunnel under the Chicago River immediately North of Van Buren street and indicated on this map as "West Chicago Street Railway tunnel." This prevented the deeping of the river for some time, as the top of the tunnel was about, as I remember, twenty feet below the surface, twenty or twenty-one feet below datum.

3435 The Sanitary District lowered the Kampsville Dam two feet and we attempted to lower the other one, but with the restrictions placed upon us by the Government we did not succeed in getting it down.

It was 1905 or 1906. And that was done pursuant to a permit from the Secretary of War.

HISTORY OF ROUTE OF NAVIGATION FROM LAKE MICHIGAN TO MISSISSIPPI, ACTS OF STATE AND FEDERAL GOVERNMENT CONCERNING ITS MAINTENANCE AND IMPROVEMENT, AND CONNECTION OF SANITARY DISTRICT'S DIVERSION WORKS WITH SUCH ROUTE.

History of the route.

By stipulation (Rec., Vol IV, p. 1813) the testimony of Professor Clarence W. Alvord, professor of history of the University of Illinois, Professor A. C. McLaughlin, professor of history of the University of Chicago and Dr. Reuben Golde Thwaites, secretary of the Wisconsin Historical Society, witnesses for the United States in the case of *United States* v. *Economy Light & Power Company* (involving the navigability of, and the jurisdiction of, the Secretary of War over the Des Plaines River) as given in that case, was introduced on behalf of the defendant Sanitary District of Chicago (Rec., Vol. IV, pp. 1814-1977).

The testimony of these witnesses established that the route now occupied by the main channel of the Sanitary District of Chicago between the Chicago River and the Des Plaines River was used from time immemorial as a route for trade and travel by water; that at a point now known as Riverside, which is approximately 39th street, Chicago, extended, where the Des Plaines River turned to the southwest, there was a small stream which in a state of nature before any improvements were made, flowed into the Des Plaines River from Mud Lake, a large stretch of water, which was from 300 feet to half a mile wide and from a mile to three or four miles in length, depending upon the wetness or dryness of the season; that in wet seasons from the easterly extremity of this marsh or Mud or Portage Lake, as it was called by the early settlers, was a stream flowing easterly, which was known as the West Fork of the South Branch of the Chicago River, so that in wet seasons

it was possible to pass in a boat from the Des Plaines River to Lake Michigan or from Lake Michigan to the Des Plaines River and in drier seasons it was at times necessary to make one or more portages in going to and fro between the Chicago River and the Des Plaines River; that this route through Mud Lake was the route (Rec., Vol. IV, p. 1814, *et seq.*) of the early explorers and the traders, trappers, and travelers who had reason to make a journey either way between the Great Lakes and the Illinois River. The exerpts set out in Volume IV show actual trips, maps, accounts of travelers, statements in public documents, contemporaneous histories, gazeteers, guide books, and the statements of individuals living on the route that the route was used as a highway for trade and travel.

Father Marquette stated that on his first voyage he came up, over this route using the Illinois River and Chicago portage to the Chicago River in 1673. (Rec. Vol. IV, p. 1816.)

Tonti, who was a lieutenant of the Cavalier de LaSalle, made use of this route in the winter of 1681. (Rec. Vol. IV, p. 1819.) The Cavalier de LaSalle himself came over the route on ice leaving the junction of the Des Plaines and Kankakee on the sixth of January, 1681, and again on the fourth of January, 1682. (Rec. Vol. IV, p. 1821.) Upon the death of de LaSalle, Father Membre and Abbe Cavalier, the brother of LaSalle, came up over this route in 1688. (Rec. Vol. IV, p. 1822.)

Father St. Cosme, in 1698, used this route from Chicago to the Des Plaines River and down the Des Plaines River to the Illinois River. (Rec. Vol. IV, p. 1826.)

Father Gravier writes that he used the route in September, 1700. (Rec. Vol. IV, p. 1829.)

John Baptiste Perrault made a trip from Chicago over to and down the Des Plaines River to Cahokia and returned over the same route in 1783. (Rec. Vol. IV, p. 1851.)

Hugh Heward, a Canadian, associated with the British fur trading houses, on May 9, 1790, describes in a diary kept by him, such a trip from Chicago across to the Des Plaines and down the Des Plaines River. (Rec. Vol. IV, p. 1852.)

Professor of History Clarence W. Alvord, of the University of Illinois, after having examined the various historical data, stated his conclusion to be that from the latter part of the 17th century through the first third of the 19th century, men engaged in the fur trade passed up and down the Chicago and Des Plaines Rivers in canoes and flatboats very regularly; that the fur trade was pursued by the French as long as they held possession of this country; was developed more fully by the English and later by the Americans; that the most active trade carried on the two rivers falls between the period of 1783 and 1825, or thereabouts; that the traders found a very easy passageway by means of these rivers in the early spring. That during the time of drought such as occurred in the summer or fall, the passage was hard, but even then they forced their boats through the waterway, often being obliged, however, to carry their packages around the shoals and rapids. (Rec. Vol. IV, p. 1929, 1930.)

Professor of History A. C. McLaughlin, of the University of Chicago, says:

> "Referring now to the period from the time of Charlevoix to the year 1825, and basing my answer upon the sources of historical information to which my attention has been specifically directed, assuming that as a historical writer I was preparing a history of Illinois, concerning the use of the Desplaines River, I should say that the Desplaines River was used with apparently considerable frequency as a route of trade and com-

merce; that at certain seasons of the year it seemed to have presented some difficulties, other seasons of the year it was used with considerable ease, and that it was a well known means of communication between the lake region and the lower Illinois and Mississippi." (Rec. Vol. IV, p. 1936)

Dr. Reuben Gold Thwaites, secretary of the Wisconsin Historical Society, states his conclusion on the same evidence as follows:

"Giving due weight to all the sources of information that I have examined my opinion is that from the latter part of the 17th century through the first third of the 19th century, men engaged in the fur trade with the western Indians actually and quite regularly passed up and down the Chicago and Desplaines Rivers in canoes and bateaux, Mackinaw boats and other boats propelled by oars, or poles, laden with merchandise and furs; that these traders and travelers found a comparatively easy passageway by means of these rivers in the early spring, and sometimes at other seasons; that during times of drought such as often occurred in the summer and fall on most of the western portage routes between the Great Lakes and the Mississippi (as, for instance, on the well-known and much used Fox-Wisconsin portage route) the passage was sometimes difficult; but even then these fur traders appear to have succeeded in forcing their boats over the Chicago-Desplaines waterway although perhaps, they were obliged here and there to make some carriage at that time of year, the length of the carriage varying greatly from season to season, and from year to year, according to the stage of water." (Rec. Vol IV. pp. 1947):

The Session of Virginia of 1783 of the Northwest Territory provided that the Northwest Territory shall

"be laid out and formed into states containing a suitable extent of territory not less than 100 nor more than 150 miles square, or as near thereto as circumstances will admit, and that the states so formed shall be distinct republican states and admitted members of the Federal Union, having the same rights of sovereignty, freedom and independence as the other states."

The Report of March 24, 1786, on the division of the Northwest Territory, adopted by Congress, among other things provided (Journals of Congress, Vol. IV, p. 663):

"Whereas it appears * * * that the laying it out and forming it into states of the extent mentioned in the resolution of Congress of the tenth of October, 1780, and in one of the conditions contained in the cession of Virginia, will be productive of many and great inconveniences; that by such a division of the country, some of the new states will be dperived of the advantages of navigation, some will be improperly intersected by lakes, rivers, and mountains, and some will contain too great a proportion of barren, unimproved land, and of consequence will not for many years if ever have sufficient number of inhabitants to form a respectable government, and entitled them to a seat and voice in the federal council: And whereas in fixing the limits and dimensions of the new states, due attention ought to be paid to natural boudaries and a variety of circumstances which will be pointed out by a more perfect knowledge of the country, so as to provide for the future growth and prosperity of each state, as well as for the accommodation and security of the first adventurers."

Article 5 of the ordinance of 1787 provided (p. 962):

"There shall be formed in the said territory not less than three nor more than five States; and the boundaries of the States, as soon as Virginia shall alter her act of cession and consent to the same, shall become fixed and established as follows, towit: The Western State, in the said terrritory, shall be bounded by the Mississippi, the Ohio and the Wabash Rivers; a direct line drawn from the Wabash and Post Vincents, due north, to the territorial line between the United States and Canada; and by the said territorial line to the Lake of the Woods and Mississippi. The middle State shall be bounded by the said direct line, the Wabash from Post Vincents to the Ohio, by the Ohio, by a direct line drawn due north from the mouth of the Great Miami to the said territorial line, and by the said territorial line. The eastern State shall be bounded by the last-mentioned direct line, the Ohio, Pennsylvania, and the said territorial line."

The following from 32 Annals of Congress, 15th Congress, 1st Session, April 3, 1818:

(P. 1677)

"STATE OF ILLINOIS.

The House resolved itself into a Committee of the Whole on the bill to enable the people of Illinois Territory to form a constitution and State government, and for the admission of such State into the Union on a footing with the original States.

Mr. Pope moved to amend the bill by striking out the lines defining the boundaries of the new States, and to insert the following:

> 'Beginning at the mouth of the Wabash river; thence up the same, and with the line of Indiana to the northwest corner of said State; thence east with the line of the same Sate to the middle of Lake Michigan; thence north along the middle of said lake to north latitude 42 deg. 30 minutes; thence west to the middle of the Mississippi river; and thence down along the middle of that river to its confluence with the Ohio river; and thence up the latter river along its northwestern shore to the beginning.'

The object of this amendment, Mr. P. said, was to gain, for the proposed State a coast on Lake Michigan. This would afford additional security to the perpetuity of the Union, inasmuch as the State would thereby be connected with the States of Indiana, Ohio, Pennsylvania and New York, through the Lakes. The facility of opening a canal between Lake Michigan and the Illinois river, said Mr. P., is acknowledged by every one who has visited the place. Giving to the proposed State the port of Chicago, (embraced in the proposed limits,) will draw its attention to the opening of the communication between the Illinois river and that place, and the improvement of that harbor. It was believed, he said, upon good authority, that the line of separation between Indiana and Illinois would strike Lake Michigan south of Chciago, and not pass west of it, as had been supposed by some geographers who had favored us with maps of that country; and, Mr. P. added, that all the country north of the proposed State, and bounded by Lakes Michigan, Huron, Superior and of the Woods, and the Mississippi river, must form but one State, Congress being restricted, by

the ordinance of 1787, from erecting more than five States in the Northwestern Territory.

This motion was agreed to without a division.

* * *

The Committe rose and reported the bill to the House, and it was ordered to be engrossed, as amended, and read a third ime, *nemine contradictente.*"

In an official report transmitted on December 28, 1819, to the House of Representatives by the then Secretary of War John C. Calhoun, is a report to the Secretary of War by Major Stephen H. Long, in which Major Long, said. (Rec. Vol. IV, pp. 1881, 1882):

"The river Desplaines is a small stream rising in the lowlands, bordering upon the west side of Lake Michigan and has its general course in a southwesterly direction. The Valley of this river has an average width of about one mile and is terminated on both sides by regular banks nearly parallel to each other, extending along the river about thirty miles from the head of the Illinois. In ascending this river, also the banks and bluffs gradually decrease in height being as before mentioned about one hundred feet high at the mouth and only 100 or 125 at the distance of thirty miles higher up the river, where, instead of maintaining their parallel direction, they form nearly right angles with the course of the river, that on the right taking an easterly, and that on left a northwesterly course; but, being gradually inflected from these courses, they form extensive curves encircling a large tract of flat prairie, in no part elevated more than twelve or fourteen feet above the common level of the water in this vicinity. The river, throughout the above mentioned distance has four or five short rapids or ripples that make their appearance only in times of low water. In every other part it has the appearance of being a chain of stagnant pools and small lakes, affording a sufficient depth of water for boats of moderate draught.

In the flat prairie, above mentioned, is a small lake, about five miles in length and from six to thirty or forty yards in width, communicating both with the river Desplaines and Chicago river by means of a kind of canal which has been made partly by the current of water, and

partly by the French and Indians for the purpose of getting their boats across in that direction, in time of
1882 high water. The distance from the river Desplaines to Chicago river by this water course is about nine miles through the greater part of which there is more or less water, so that the portage is seldom more than three miles in the driest season, but in the wet season boats pass and repass with facility between the two rivers."

REPORT OF R. GRAHAM, ASSISTANT SECRETARY OF WAR, AND
1884 JOSEPH PHILIPS, CHIEF JUSTICE OF ILLINOIS.

The next report attached to this same document is the report of R. Graham and Joseph Philips. Philips was one who accompanied this expedition of Major Long and made a report likewise on the subject. He was the first Chief Justice.

The said report of Graham and Philips of April 4, 1819, in part is as follows:

1885 "It was, however, determined, from certain data, that the level of the river was two feet, or thereabouts, above the level of the lake. From this view it would seem that the cutting of a canal in this place between the Plein and the Lake would be a work of neither skill, difficulty or expense. Small, however, as the labor would be under this view it is still diminished upon a close examination, and by finding that an arm of the lake called Chicago puts out in the direction of the Plein and that an arm of the Plein, also called Chicago, puts out in the direction of the lake. They approach within two miles of each other; so that, in common water, there is only dry ground to that extent between them. The character of these two arms is essentially different; that of the lake being about sixty feet wide, and from ten to forty feet deep; that of the river, being in high water, from four to six feet deep, and in, places a mile wide, and, in low water, either dry or reduced to a gutter. Between the heads of these two arms is also a gutter, which is dry in the dry seasons of summer and fall, and full of water in the spring, and, when thus filled with water, the boats, of six or eight tons, engaged in the Mackinaw and Mississippi trade, run through, backwards and forwards, so as to make no portage between Mackinaw and

the Mississippi. This gutter, judging from the appearance of others now forming, was, at first, a path worn out by the feet of those who carried things across the
1886 portage, and afterwards deepened by the attrition of the waters until formed into a little canal. The wind, alone, gives the water a current in this little canal, and its direction depends upon the course of the wind. Objects have been seen to float out of it from the same point to the river and to the lake.

It is incontestably true, that an east wind will drive the water of the lake through this gutter into the Plein, and that water from Lake Michigan has been discharged by this outlet into the Mississippi, and thence into the Gulf of Mexico. It is equally incontestable, that the waters of the Plein have been driven, by the same channel, into the lake; and these phenomena may now be witnessed, at any time, when the waters are high and the wind blows hard. It follows, therefore, that to finish the canal began by nature, in this place, would require, as we have already said, but little of skill, time or expense."

In 1795, Anthony Wayne, Major General of the United States, made a treaty of peace, known as the Treaty of Greenville, with the several Indian tribes then living in the Northwest Territory (Illinois, Indiana, Ohio, Michigan and Wisconsin) which provided for a free passage by water over this water route between the Chicago River and the Des Plaines River. (Rec. Vol. IV, p. 1861, 1862):

In 1816 the United States made a treaty of peace with the Ottawa Indians whereby the land in which the Sanitary District Canal is now located was ceded to the United States. (Rec. Vol. IV, p. 1874):

Right of Navigating St. Lawrence by citizens of the United States denied by Great Britain.

By acts of Parliament in 1822 and 1824 the British Government denied the citizens of the United States the free navigation of the St. Lawrence between the Great Lakes and the Sea.

In a communication between Minister Rush and Mr. Adams, Mr. Rush, says (Rec. Vol. IV, p. 2276):

Extracts from Message of the President of Jan. 7, 1828, State Papers 1st Session 20 Congress, Vol. 2, Doc. 43, Page 8, entitled "Extract of a Dispatch from Mr. Rush to Mr. Adams, Dated London, August 12, 1824."

"The act of parliament of August 5, 1822, having immediate relation to the commercial intercourse between the United States and the British continental possessions in their neighborhood, I naturally regarded it as your instructions to me had done in connection with the act of June 24, 1822. This brought under consideration our claim to the navigation of the St. Lawrence. Between this question and the questions of commercial intercourse under the act of June, 1822, the British plenipotentiaries were constantly unwilling to acknowledge any connection. Nevertheless, looking to your instructions, and as well to the reason of them as to their authority, I treated the two questions as belonging to one and the same general subject. They asked whether, taking the two acts of parliament together, the United States did not already enjoy the navigation of this river? I said that they did; by the act of June 24, 1822, they enjoyed it from the ocean to Quebec; and by that of August 5, 1822, from any part of the territories of the United States to Quebec. But from the fact of the colonial government in Canada being invested with a discretionary power to withdraw the latter of these concessions by excepting any of the Canadian ports from those to which our vessels were made admissible, it followed that our enjoyment of the navigation of this river was rendered contingent upon British permission."

The negotiations began by Mr. Rush were concluded by Mr. Gallatin and resulted in the refusal of the British to permit longer the free navigation of the St. Lawrence River. Mr. Gallatin say (Rec. Vol. IV, p. 2294):

EXTRACT OF LETTER FROM MR. GALLATIN TO MR. CLAY, DECEMBER 21, 1827.

"The British plenipotentiary will not entertain any proposition respecting the navigation of the St. Lawrence founded on the right claimed by the United States to navigate that river at the sea."

EXTRACT OF LETTER FROM MR. GALLATIN TO MR. CLAY, OCTOBER 1, 1827.

"The British plenipotentiary reply that however well disposed Great Britain might be to treat with the United States respecting the free navigation of the St. Lawrence as a question of mutual convenience, yet the views of the British government, being the same now as they were in 1824, and they being prohibited by express instructions from entering into any discussion respecting the free navigation of the river, if claimed as heretofore by the United States on the ground of right, they could not entertain any proposition to that effect if now made by me. * * *"

Acts of Federal Government and Illinois concerning establishment, maintenance and improvement of Illinois Michigan Canal.

On March 30, 1822, the Congress of the United States passed an act authorizing the State of Illinois to open a canal to connect the Illinois River with Lake Michigan, which act provided among other things, as follows (Rec. Vol. VIII, p. 67):

"Act of March 30, 1822

(3 U. S. Stat. at Large, p. 659)

An Act to Authorize the State of Illinois to Open a Canal Through the Public Lands to Connect the Illinois River with Lake Michigan. (Approved and in force March 30, 1822.)

Section 1. Be it enacted by the Senate and the House of Representatives of the United States of America, in Congress Assembled: That the State of Illinois be, and is hereby authorized to survey and mark, through the public lands of the United States, the route of the canal connecting the Illinois River with the southern bend of Lake Michigan; and ninety feet of land on each side of said canal shall be forever reserved from any sale to be made by the United States, except in the cases hereinafter provided for, and the use thereof forever shall be, and the same is hereby vested in the said State for a canal, and for no other purpose whatever; on condi-

tion, however, that if the said State does not survey and direct by law said canal to be opened, and return a complete map thereof to the treasury department, within three years from and after the passage of this act; or, if the said canal be not completed, suitable for navigation within twelve years thereafter; or, if said ground shall ever cease to be occupied by, and used for, a canal suitable for navigation; the reservation and grant hereby shall be void and of none effect; Provided, always, and it is hereby enacted and declared, that nothing in this act contained, or that shall be done in pursuance thereof, shall be deemed or construed to imply any obligation on the part of the United States to appropriate any money to defray the expenses of surveying or opening said canal; **Provided, also, and it is hereby further enacted and declared, that the said canal, when completed, shall be and forever remain a public highway for the use of the Government of the United States, free from any toll or other charge whatever, for any property of the United States, or persons in their service passing through the same."**

In 1826 the legislature of Illinois petitioned the Congress of the United States for an additional act for the construction of a canal. The other act of 1822 had ceased to have any force or effect because of the failure of the state to act within the time required. (Rec. Vol. IV, p. 2017.)

MEMORIAL OF ILLINOIS.

"The memorial of the General Assembly of the State of Illinois respectfully represents: That the construction of a canal, uniting the waters of Lake Michigan with the Illinois river, will form an important addition to the great connecting links in the chain of internal navigation, which will effectually secure the indissoluble union of the confederate members of this great and powerful Republic."

In 1827 the Congress of the United States passed an additional act authorizing the opening of the canal and the granting of public land to the State of Illinois in aid of such a project. The act is as follows (Rec. Vol. VIII, pp. 68, 69):

ACT OF MARCH 2, 1827.

"(4 U. S. Stat. at Large, p. 234)

An act to grant a quantity of land to the State of Illinois for the purpose of aiding in opening a canal to connect the waters of the Illinois River with those of Lake Michigan. (Approved and in force March 2, 1827.)

Section 1. Be it enacted by the Senate and House of Representatives of the United States of America, in Congress Assembled, That there be and hereby is granted to the State of Illinois, for the purpose of aiding the said State in opening a canal to unite the waters of the Illinois River with those of Lake Michigan, a quantity of land equal to one-half of five sections in width, on each side of said canal, and reserving each alternate section to the United States, to be selected by the Commissioner of the Land Office, under the direction of the president of the United States, from one end of the said canal to the other; and the said land shall be subject to the disposal of the Legislature of the said State, for the purpose aforesaid, and no other; Provided, *That the said canal when completed, shall be and forever remain a public highway for the use of the Government of the United States, free from any toll, or other charge, whatever, for any property of the United States, or persons in their service passing through the same;* Provided, That said canal shall be commenced within five years and completed in twenty years, or the State shall be bound to pay to the United States the amount of any lands previously sold, and that the title to purchasers under the State shall be valid.

(Duty of the Governor of the State when the canal is located, etc.)"

On January 9, 1836, the State Legislature of Illinois passed an act for the construction of the Illinois and Michigan Canal. Record Vol. IV, pp. 2295-2304. Section 16 of said act provided as follows (Rec. Vol. IV, p. 2298):

"SEC. 16. (DESCRIPTION—PROVISO.) The said canal shall not be less than forty-five feet wide at the surface, thirty feet at the base and of sufficient depth to insure a navigation of at least four feet, to be suitable for ordinary canal boat navigation, to be supplied with water

from Lake Michigan and such other sources as the canal commissioners may think proper, and to be constructed in the manner best calculated to promote the permanent interest of the country; reserving ninety feet on each side of said canal, to enlarge its capacity, whenever in the opinion of the board of canal commissioners, the public good shall require it; *provided,* that all persons who have purchased, or shall hereafter purchase lands fronting the said canal shall be permitted to lease from the said board the said reserved ground on each side of said canal, from year to year, or until the said ground shall be wanted to enlarge the capacity of said canal, for the best price that can be obtained to be paid into the canal fund."

Physical and health conditions at Chicago.

The physical conditions prior to the projection of the Sanitary District works are stated in the testimony of Lyman E. Cooley (Rec. Vol. III, pp. 1710, 1711) as follows:

The Chicago River basin, as it originally existed in nature, consisted of the North Branch and its drainage basin, together with the South Branch, an area of about 240 square miles (now about 300 square miles). West of the Chicago River basin, was the Des Plaines River basin, drained by the Des Plaines River which ran parallel to the lake from the headwaters in Wisconsin down to a point about ten miles from Lake Michigan at Lyons; and then leading southwesterly to a junction with the Illinois River, or to the junction with the Kankakee River, which formed the Illinois.

This Des Plaines River, in the vicinity of Lyons, had a low water elevation of about eight feet, and a drainage area of 633 square miles.

The divide between the Des Plaines River and the Chicago River was in the vicinity of the Bridewell, just west of Kedzie avenue, and had an original elevation of about 10½ feet above Lake Michigan, and whenever the Des Plaines River rose from two or three feet above low water, or exceeded a volume of about 1,000 second feet, the flow of the

river divided, part of it coming through the South Branch of the Chicago River to Lake Michigan, and in great floods sixty to seventy per cent of the entire flow of the Des Plaines River came to Chicago.

This condition existed up to about 1854, after the Illinois and Michigan Canal had been opened in 1848, when the Drainage Commissioners cut out the original divide at Kedzie avenue and drained out the Mud Lake region as it was known in Voyageur's days, and on the original land maps as "Portage Lake, Portage Swamp, and Portage Slough."

For a number of years thereafter, the entire flow of the Des Plaines River came in the direction of Chicago except at such times as in the fall and winter when the ice interests of the Des Plaines River Valley made a temporary dam in order to fill the ponds on the twelve-mile level between Summit and Lemont, for ice-making purposes.

Finally the flow from this source became such a nuisance to the City of Chicago that after 1870 they constructed the Ogden-Wentworth Dam. That crossed the old Portage Slough at the range line at Summit, at an elevation of something over eleven feet above Chicago datum. And this was overflowed also, whenever the river rose above a volume of about 1,000 feet per second; and the waters continued to come this way in flood times when the volume exceeded that amount until 1893 when the Sanitary District executed its river 1711 diversion and created a spill-way above Summit, which restricted the flow down the river until the volume reached between 3,000 and 4,000 feet per second. And in about 1909, this was finally closed, so that no waters from that source have come through the Chicago River to Lake Michigan since.

The effects of this overflow have been most pronounced and is noted from time to time in the narratives relating to Chicago and its portage.

The Illinois and Michigan Canal was constructed and opened in 1848. Lyman E. Cooley (Rec. Vol. III, p. 1713) testified as follows:

There was another event happening about this time, the opening of the Illinois and Michigan Canal in 1848. The first shovel had been thrown on this canal at Bridgeport within the present city limits July 4, 1836; and that had contributed greatly to the growth of Chicago during its construction."

In 1861 the Illinois Senate and House of Representatives passed a joint resolution with reference to a survey of the Illinois, Des Plaines and Chicago Rivers for the purpose of improving navigation from Chicago to the mouth of the Illinois River. (See Laws of Illinois, 1861-63, p. 277.)

"RESOLVED BY THE SENATE, THE HOUSE OF REPRESENTATIVES CONCURRING HEREIN, That the board of trustees of the Illinois and Michigan Canal be and are hereby authorized and instructed to cause prompt and thorough surveys, examination and estimates to be made of the Illinois River, and of the Illinois and Michigan Canal, and also of portions of the Desplaines and Chicago rivers, and of the portage between said rivers, for the purpose of accurately ascertaining the comparative value, cost, efficiency, benefits, and advantages, direct, prospective and incidental, of the different methods proposed or desirable for improving the navigation of the Illinois River, by dredging or excavation of the channel and wing dams, *or by supplying water from Lake Michigan, through the enlargement and deepening of the Illinois and Michigan Canal, or otherwise, or by opening a channel from Lake Michigan, by way of the south branch of the Chicago river and Mud Lake to the Desplaines river, and down said canal to a point that will secure a free, flowing, ample and never failing supply of water, sufficient for the navigation of the Illinois river at all seasons and times,* when not obstructed by ice.

* * *

and to include also an estimate for the channel hereinbefore mentioned, of sufficient size to admit of full and free steamboat navigation from the Illinois river to Chicago and Lake Michigan, *as well as a size sufficient for supplying water for all the deficiencies of navigation in the Illinois river, at all seasons.* * * *"

The Illinois and Michigan Canal originally was built upon the shallow cut plan and did not take water from Lake Michigan by gravity flow at first. Mr. Cooley testified (Rec. Vol. III, p. 1716) as follows:

The Illinois and Michigan Canal, as it was finally completed under the canal trustees, had a summit level eight feet above Lake Michigan, and it was fed in ordinary seasons from the Des Plaines River and by a feeder through the Sag Valley and the Calumet River at Blue Island.

That was known as the Shallow Cut Plan.

A dam was built across the Calumet River at an elevation of eleven feet above Chicago datum. This was insufficient in the dry seasons, and a Dutch wheel or lift wheel was erected at Bridgeport, at the forks of the Chicago River and at the head of the canal for the purpose of supplementing the feed water of the canal, and in such seasons that was sufficient in cleansing the Chicago River and as I have stated, these were operated for that purpose in the later fifties.

But in 1863, after Chicago had established a Board of Public Works, the Chicago River became very offensive. An erysipelas epidemic occurred, which was co-terminus with the South Branch and was attributed to the blood and other matters from the slaughtering houses, and it was depicted on the spot maps as the "Valley of Death."

The Board of Public Works at that time made an arrangement with the Canal Trustees by which the Bridgeport Pumping Station should be operated and the city would contribute to the cost of doing so for the purpose of cleansing the Chicago River; and that arrangement continued up to the time that the canal deepening was completed in July, 1871.

That was completed then on the Deep Cut Plan.

On April 16, 1865, the State of Illinois passed an act to provide for the completion of the Illinois and Michigan Canal upon the plan adopted by the state in 1836 which authorized the City of Chicago to deepen the Illinois and Michigan Canal

in order to purify and cleanse the Chicago River by withdrawing a greater quantity of water from Lake Michigan. Said act is as follows (Rec. Vol. VIII, pp. 70, 71):

"An Act to Provide for the Completion of the Illinois and Michigan Canal upon the Plan Adopted by the State in 1836. (Approved February 16, 1865, in Force April 16, 1865.)

(Preamble.)—Whereas, it has been represented that the City of Chicago, in order to purify or cleanse Chicago River, by drawing sufficient quantity of water from Lake Michigan, directly through it, and through the summit division of the Illinois and Michigan Canal, would advance a sufficient amount of funds to accomplish this desirable object; and,

Whereas, the original plan of the said canal was to cut down the summit so as to draw a supply of water for navigation directly from Lake Michigan, which plan was abandoned for the time being, after a large part of the work had been executed, only in consequence of the inability of the State to procure funds for its further prosecution; and,

Whereas, under the law creating the trust the plan of the summit division of the canal was changed, the level being raised so as to require the principal supply of water to be obtained through the Calumet feeder, subject to serious contingencies, and by pumping on to the summit with the hydraulic works at Bridgeport; now, therefore,

(Summit Division to Be Completed.)—Section 1. Be it enacted by the People of the State of Illinois, represented in the General Assembly: That to secure the completion of the summit division of the Illinois and Michigan Canal, upon the original 'deep cut' plan, with such modifications and changes of line, if necessary, as will most effectually secure the thorough cleansing or purification of the Chicago River, and facilitate the execution of the work, the City of Chicago, through its constituted authorities, may at once enter into an arrangement with the board of trustees of said canal, with a view to the speedy accomplishment of the work.

(Opening and Closing of Canal.)—2. The canal shall not be constructed of a less capacity than the plan adopted by the canal commissioners in 1836, nor shall the work of deepening it be prosecuted so as to materially interfere with the navigation. By consent of the board

of trustees, however, the navigation may be opened later and closed earlier than usual in former years, but it shall never be diminished to a less time than six months.

(Right of Way.)—3. It shall be lawful for the City of Chicago to enter upon and use any lands which may be necessary for the right of way for said canal, if the route should in any part vary from the present line of canal, and to take and use any materials of any description, necessary for the prosecution of the work contemplated, along the line thereof; the value of the same to be determined in the mode provided by the general laws of this State."

February 12, 1867, in an official report made to the Chief of Engineers of the War Department of the United States by Major Gen. J. H. Wilson, United States Engineer, who had been instructed to make a survey of the Illinois River, pursuant to the Act of Congress, June 23, 1866, Major Gen. Wilson said (Rec. Vol. IV, p. 2242):

"The Illinois River seems to have been specially designed by nature as the line by which the waters of Lake Michigan are to be connected with those of the Mississippi. Its two principal tributaries, the Des Plaines and the Kankakee, rising the one in Wisconsin and the other in Indiana, run for many miles almost parallel with the western and southern lake shore, and are separated from the lake basin by a ridge of insignificant height and width. A moment's consideration will show that at no remote period the waters of the lake must have been carried off by these streams as well as by the St. Lawrence. It has been already shown that the highest point of this ridge on the line of the Illinois and Michigan Canal is only 14 feet above the ordinary level of the water in the Chicago River at Bridgeport, and it is by no means certain that a lower line may not be found by a careful survey. In fact, it is the opinion of many old contractors who are well acquainted with the entire region, that a much more favorable location for a steamboat canal can be obtained from Bridgeport to Section 46 of the present canal, by following the line through Mud Lake. But let this result be as it may, the data herein contained, together with the existence of a canal of limited capacity already in operation, demonstrate beyond a doubt that the waters of the lake may be carried into the Illinois River through a navigable

channel of any required dimensions, and at a cost which cannot be regarded as excessive when the objects to be obtained are duly considered.

As all the lockage will be descending from the lake, it is apparent that the only limit to the capacity of the canal will be that which depends upon the velocity with which the locks can be filled and emptied. The summit will be inexhaustible, and this cannot be said of any other practicable line of water communication between Lake Michigan and the Mississippi."

The Deep Cut plan for the Illinois and Michigan Canal was carried out and completed in 1871 by the City of Chicago, to take more water from Lake Michigan by gravity as stated by Mr. Cooley (Rec. Vol. III, pp. 1718, 1719) as follows:

Meantime, a Commission had proposed the deepening of the Illinois and Michigan Canal on the original deep cut plan; and in 1865 an enabling act was procured from the General Assembly which authorized the City of Chicago to deepen this canal on the original plan for sanitary purposes; and the City of Chicago did so, and expended thereon about $3,000,000 in cash and opened the same in July, 1871.

Pursuant to the River and Harbor Act of 1875, Col. J. N. Macomb, made a report to the Chief of Engineers and by him transmitted to Congress, in which he said (Rec. Vol. IV, pp. 2243, 2244, 4748-4750):

"Report of Colonel J. N. Macomb, Corps of Engineers.

Rock Island, Ill., January 25, 1875.

General: I have the honor to present herewith the report of Mr. F. C. Doran, assistant engineer, who was charged by me with the duty of making the surveys and estimates for the Hennepin Canal Route, and particularly for the extension to Chicago.

In considering the Hennepin Canal as a part of the water-communication desired for connecting some point of the Mississippi River near Rock Island, with Lake Michigan, at Chicago, it appears that the basin at Hennepin is about 100 feet below the level of the Mississippi River in the vicinity of Rock Island, and nearly 140 feet below the level of Lake Michigan.

2244 • • •

The improvement of the eastern portion of the Illinois and Michigan Canal involves the further cutting down of the summit level and enlarging the waterway so as to afford an unfailing supply of water from Lake Michigan for the improved Illinois River.

Report of Mr. F. C. Doran, Assistant Engineer.

Rock Island, Ill., January 9, 1875.

Page 96.

Colonel: I have the honor to submit the following report upon the examination and survey of a route for a canal between Lake Michigan and the Mississippi River, together with the survey of a portion of the Illinois River. * * *

2247 Page 97.

Prior to the year 1872, the summit-level of the Illinois and Michigan Canal was some 8 feet above the standard-level of Lake Michigan, and the quantity of water requisite to maintain navigation on the summit-level of the canal was supplied from Lake Calumet by a feeder and from the Chicago River by expensive pumping-machinery.

Sometime during the year 1866, the Board of Public Works of the City of Chicago entered into a contract with the State to cut down and reduce the summit-level of the canal to the elevation of the lake.

The object of this work on the part of the city authorities was to obtain an outlet for the south branch of the Chicago River; that being a receptacle for the sewerage of a large part of the city.

This contract was satisfied, the work completed, and navigation on the canal resumed July 18, 1872. The exertions and labors of the city to rid itself of a nuisance were not in vain; the residents of the city were relieved of a truly great evil, and the problem of securing a permanent and ample supply of water for the canal was practically solved.

Happy as such results were, the work, from its con-
2248 tracted dimensions afforded only partial relief; and recent drainage improvements in the vicinity of the city have proved quite detrimental to and interfered very seriously with the city's purposes and interests in respect to this work.

In view of the many benefits that would accrue to the city in case of a further enlargement of this canal, as contemplated, the question is believed to be pertinent, will the city assume her portion of the cost of such enlargment?

One of the important duties of this survey was to determine accurately the volume of water to be drawn from the lake to maintain a depth of water in the river after it should be improved.

Experience on the summit-level of the canal, since it has been supplied from the lake, proves conclusively that the varying stages of water in the lake very materially affect navigation on this part of the canal. This fact is more noticeable during periods when the direction of the wind is parallel with the axis of the canal; the fluctuations in the elevation of the surface of the water being directly traceable to this cause."

In an extract from U. S. Chief of Engineer's Report, 1880, made pursuant to Rivers & Harbors Act of March 3, 1879, Appendix EE, Page 1995, survey of Illinois River, Major G. J. Lydecker said (Rec. Vol. IV, p. 2248):

"United States Engineer Office.

Chicago, Ill., May 10, 1880.

General: I have the honor to submit the following report on a survey of the Illinois River, executed in pursuance of the act of Congress making appropriations for the improvement of certain rivers and harbors, approved March 3, 1879.

The question of a through line of water communication from the Mississippi to Lake Michigan, via the Illinois River, has been before Congress since an early date. In 1822, the State of Illinois was authorized to make through the public lands of the United States a route for a navigable canal connecting the Illinois River with Lake Michigan, and between that date and 1854, Congress had granted to the State 321,760 acres of land to assist in its construction. The canal was first opened to navigation in 1848, its cost up to that time being $6,409,509.95; since then the state has spent a great deal towards its enlargement and maintenance. In the meantime several surveys, having in view the improvement of the Illinois River, have been made, the first in 1838 by Capt. Howard

Stansbury, Topographical Engineers; the next of any considerable importance was made under the direction of General J. H. Wilson, in 1866, the object of which was 'to obtain such specific and accurate information in
2249 regard to obstructions to navigation in that river as will enable you to submit estimates for its improvement, so that the largest boats navigating the Illinois and Michigan Canal, and steamboats drawing four feet of water, will be enabled to pass through the river to St. Louis during the season of extreme low water without breaking cargo.'

His report on this survey led Congress to direct a more complete survey in 1867 (act approved March 2), the object of which was to prepare plans and estimates 'for a system of navigation by way of the Illinois River, between the Mississippi and Lake Michigan, adapted to *military, naval,* and *commercial* purposes.' This duty was committed to a Board of Engineers composed of General J. H. Wilson and Mr. William Gooding, Civil Engineer, the latter having been for a long time the Chief Engineer of the 'Illinois and Michigan Canal.' The report of this Board was submitted to the Chief of Engineers under date of December 17, 1867, and is published in his annual report for 1868, pages 438 to 468. It recommended that the Illinois River be improved by the construction of five locks and dams, creating thereby a slack water system with a navigable depth of 7 feet at the lowest stage, from the mouth of the river at Grafton to Utica, 227 miles above; the lock chambers were to be 350 feet long, 75 feet wide, and the estimated cost of the entire work was $1,953,600. To complete the through line to Lake Michigan, an enlargement of the canal was recommended, the estimated cost of this enlargement being, in round numbers, $16,250,000.

No appropriations were made by Congress to carry out the plan of improvement above indicated, but the State of Illinois, in substantial conformity with that plan, has constructed *two* of the proposed locks and dams (viz, at Henry and Copperas Creek), at a cost of $747,747, while the annual appropriations by Congress for improving the Illinois River (aggregating to date $589,150) have been applied mainly to ameliorating its navigable condition by dredging channels through the worst bars, and constructing dikes and wing-dams for contracting the waterway. For a more detailed description of these operations I would respectfully refer to my report dated

August 30, 1878 (which was published as House Ex. Doc. No. 81, 45th Congress, 3rd Session), a copy of which is transmitted herewith.

The several surveys and reports above referred to
2250 gives so complete a description of the physical characteristics of the route, and present the arguments in favor of its improvement so forcibly, that it seems unnecessary to extend this report by repeating what has been so fully set forth before; accordingly it is limited to a brief outline of operations on the last survey, and a statement of what is necessary to complete the improvement of the river.

A substantial improvement having been effected from its point of connection with the canal down to Copperas Creek Lock, it was decided to apply the $5,000 allotted for our survey to the remainder of the river, viz, from Copperas Creek to Grafton, where the Illinois empties into the Mississippi.

* * *

Page 1998.

The laws of Congress require that reports of surveys of rivers and harbors shall contain 'statements of all existing facts tending to show to what extent the general commerce of the country will be promoted by the several works of improvements contemplated by such examinations and surveys.' In fulfillment of this requirement, it seems only necessary to note that the improvement of the Illinois River, supplemented by the enlargement of the Illinois and Michigan Canal as heretofore proposed, will furnish a reliable and commodious channel of water communication from the Mississippi River to the Northwestern lakes; by this time the vast Mississippi Valley, and all the country tributary thereto, is brought into direct water communication with Lake Michigan, at the great City of Chicago, with its flood of commerce eastward and westward; the route exists as a practicable one of considerable importance today, and the question is simply one of enhancing its value by increasing its capacity to a degree commensurate with the important interests involved.

Other routes have been examined and studied with care but neither of them occupies so central a position, can be built so soon, and with such certain results, maintained so economically, nor utilized through so great a part of the year.

Considering this simple statement, the facts so fully set forth in previous elaborate reports, and noting the wonderfully rapid development of the entire western country, it would seem that nothing further is necessary to indicate 'to what extent the general commerce of the country will be promoted' by the contemplated improvement, nor to show how desirable it is that the work should be accomplished with the least delay practicable."

In 1881 the State of Illinois passed a resolution authorizing City of Chicago to furnish the canal with 60,000 cubic feet of water per minute by means of pumps. (Rec. Vol. VIII, pp. 72, 73; this Narrative, p. 49.)

January 30, 1887, the Drainage and Water-Supply Commission rendered a report, in which the resolution of the City of Chicago City Council authorizing the Commission and the appointment by the mayor are set out as well as the findings of the Commission.

Said report is as follows (Rec. Vol. I, pp. 496-522):

"Chicago, January 30, 1887.

To the Honorable Mayor and City Council of the City of Chicago:

Gentlemen: On January 27, 1886, your honorable body passed a resolution authorizing the creation of a drainage water-supply commission. After being amended, February 23, it read as follows:

Whereas pure water and scientific drainage are necessities of this community, and the people demand a system of water supply and drainage adequate to meet the requirements not only of the present, but of years to come, nor will any temporary expedient or makeshift satisfy them; and

Whereas a thorough and permanent system of supplying pure water to our citizens and caring for the drainage of the municipality can not be paid for out of current taxation, therefor it is desired that a plan shall be devised and perfected before the next meeting of the legislature to the end that necessary legislation may be had.

For the purpose of carrying into effect the objects sought, there is recommended the appointment by the Mayor of a commission to consist of one expert engineer, whose reputation is so high that his opinion and report will command the respect of the community, and with him one or two consulting engineers of like experience in engineering and sanitary matters. The duty of this drainage and water supply commission, made up as above set forth, should be to consider all plans relating to drainage and water supply which may be brought to its attention; to make such examinations and investigations and surveys as may be deemed necessary; to collect all information bearing on this problem; to consider all recent developments in the matter of sewage disposal, and their
497 application to our present and future needs; to consider and meet necessity of increasing our water supply and of protecting the same from contamination; to remedy our present inadequate methods of drainage and sewage disposal; to consider the relations of any system proposed to adjacent districts, and whether there may not be a union between the city and its suburbs to solve the great problem; to determine the great question as to the interest which the State and the United States may have in the disposal of sewage by way of the Illinois River, and to devise plans to meet any objections thereto, if such a system shall be thought best; and in general to consider and report upon any and all things which relate to the matter of water supply and drainage of the City of Chicago.

The commission should report on the whole matter committed to it in the most full and comprehensive manner, with maps, plans, and diagrams complete, and accompany the report with estimates of the first cost and annual requirements for the maintenance of the system proposed.

The report of the commission should be made as early as practicable, and not later than the convening of the next session of the Illinois legislature, in January, 1887.

In consideration of the foregoing, be it,

Resolved, That the Mayor be, and is hereby, authorized and directed to employ on behalf of the city one expert engineer of reputation and experience in engineering and sanitary matters, at a salary not to exceed $10,000 per annum, and also to employ such consulting engineers, not exceeding two in number, as may seem necessary, and such assistant engineers as may be re-

quired, all to be paid according to services rendered, for the purpose of carrying out the objects set forth in the preamble hereto. For the fees of said assistant engineers and for all expenses connected with said work there shall be allowed not to exceed the sum of $20,000. All fees, salaries, and expenses connected with said work shall not exceed in the aggregate the sum of $30,000, and the same shall be paid from the water fund of the city upon vouchers audited by the Mayor and city comptroller.

In accordance with the terms expressed herein his honor, Carter H. Harrison appointed Rudolph Hering as chief engineer, Benezette Williams and S. G. Artingstall
498 as consulting engineers, who together should constitute a commission. Mr. Hering entered upon duty March 28, Mr. Williams September 17, and Mr. Artingstall December 21, 1886.

The investigation designated by the resolution was a formidable one, composing no less a task than the consideration of the entire subject of the future water supply and drainage of Chicago. It appeared doubtful from the beginning that a report such as was demanded could be furnished within the specified time, for the simple reason, if for no other, that observations of the lake phenomena and of the flow of certain rivers should be extended over at least one year, covering four consecutive seasons, in order to draw satisfactory deductions.

But the large amount of work alone that was asked for made it impracticable to present a complete report in so short a time. It was expected, however, that results could be reached sufficient to indicate the character of legislation required to carry out any project that might be determined upon, and that therefore a preliminary report having this end in view could be made at the stated time, leaving to a later date the presentation of a report outlining the detailed features of the scheme recommended and embracing the minor results of the entire inquiry.

The present communication is to cover the ground indicated for the preliminary report, and besides containing the conclusions reached regarding the main features of the proposed project, it contains also a brief review of the work done during the past year and of what still remains to be done.

The month of April was devoted to a general examination of the subject of the territory to be investigated, and

of the various suggestions that had been made toward effecting a solution of the problem.

The examination disclosed the fact that the city is sometimes greatly suffering from the offensive condition of parts of the Chicago River and its branches, caused by the discharge of sewage into the same, and from the occasional contamination of its water supply, brought about by the discharge of the polluted contents of the river into the lake. It also disclosed the fact that almost every conceivable way of dealing with these questions had been suggested and in some forms applied during the past thirty years.

[The problem therefore demands the attainment of two
499 ends—the protection of the water supply and the removal of the river nuisance. As the water must be taken from the lake, it is evident that both its pollution and the objectionable condition of the rivers should be prevented by a better disposition of the sewage. It is, therefore the latter question which constitutes the main object of this investigation.

Among the possible methods of getting rid of the Chicago sewage there are but three that have been deemed worthy of an extended consideration, namely: A discharge into Lake Michigan, a disposal upon land, and a discharge into the Des Plaines River. The preliminary work has, therefore, been confined to these three projects, and was classed as topographic, hydrographic, and miscellaneous.]

At the time when the present commission began its labors the topographical work had already received some attention. Surveys were being made of the Des Plaines River from Bridgeport westward under the direction of Mr. Artingstall, city engineer. These surveys were continued, and have now been completed as far as Joliet. They include contours of the entire valley and borings to rock between Bridgeport and Lemont. In order to understand the hydrography of the Des Plaines Valley above the point where the Chicago sewage could be discharged into it, and also to ascertain the probable magnitude and effect of floods in the river, a survey was made of its bed as far north as Northfield township. To determine the area of the basin its entire divide was located. To ascertain the practicability of diverting the flood waters from the upper portion of the Des Plaines and North Branch water sheds directly into the lake, and thus avoiding the difficulties which would arise from their passing

through the Chicago River, all feasible lines were surveyed. Finally, a few levels were taken of the area adjoining the city wherever no connected levels existed to show the general topographical features of the territory over which the future city will spread out and from which the drainage will require artificial removal.

[The hydrographic work consisted in ascertaining the flow of the Des Plaines River, the rainfall upon its area, its flood discharges, the character of its bed, and the probable effect of discharging the Chicago sewage into it when diluted by a large and constant stream of water from the lake. It consisted, further, in examining the
500 nature of the currents in the lake and in studying the rise and fall of its level, and in ascertaining the amount and character both of the sewage discharged into it and of the deposits in the river and lake in front of the city to determine the effects of the present sewage disposal.

Inquiry and surveys were made to show the feasibility of purifying the Chicago sewage by filtration on land.] Land damages were carefully estimated for the different schemes; existing records were searched concerning borings and excavations made in and about the city, so that the practicability of certain lines of tunnels could be discovered; the probable growth of the city and its suburbs, as well as the probable distribution of the future population, received a careful attention, and, finally, a large number of data were compiled which pertain to the existing works of water supply and sewerage in Chicago and the adjoining towns.

In reporting the result thus far gained we will present them in the order most convenient for discussion, but before doing so will briefly describe the present manner and effect of the sewage disposal, as shown by this investigation.

Present Sewage Disposal.

The sewage works of Chicago and suburbs have been planned on what is called the combined system, in which the sewers serve for the removal both of sewage and rain water. In the town of Evanston they empty into the lake. In the town of Lake View they partly discharge into the lake and partly into the North Branch. From the north and west divisions and part of the south division of Chicago, the drainage enters the Chicago River and its branches, and from the remaining part of the

south division it flows into the lake at three outlets, situated respectively, at Twelfth, Twenty-second, and Thirty-fifth streets. The sewers of Hyde Park discharge into the lake excepting those of Pullman, where the sewage is disposed of on land. The town of Lake, including the Stock Yards district, drains into the South Fork of the Chicago River.

When the sewage works of this city were designed, in 1856, by Mr. E. S. Chesbrough, it was apprehended that ultimately some means would have to be found to change the water in the river from time to time or to keep the sewage entirely out of it. The first step toward improv-
501 ing the condition of the river was taken by deepening the Illinois and Michigan Canal, so as to cause a current from the lake to the Des Plaines River at Lockport. The next step was the building of the Fullerton avenue conduit in order to produce a circulation in the North Branch; and the last step was the erection of the canal pumping works to increase the flow in the river, which had become greatly polluted.

The influence of these works is confined to the main river and its north and south branches. But the south fork of the latter, receiving a large amount of sewage from Chicago and the town of Lake, and charged with the waste from the Union Stock Yards and packing houses, has no artificial means for a circulation of its water, and as a consequence is in a condition of great filthiness.

The accompanying diagram (a) has been prepared to show the present pollution of the Chicago River and its branches during the time when all of their water is discharged into the canal by the Bridgeport pumps. On the left are shown the main river and the north branch, one above the other, their combined waters forming the south branch, and reaching Bridgeport on the right, where they are lifted into the canal.

At the latter point the south fork is shown as joining it. The shaded portions indicate the amount of sewage entering and passing the respective points, and the blank portions the lake water diluting it. The degree of dilution is shown by the relative areas. It diminishes in the north branch from Fullerton avenue to the south branch, and becomes still less toward Bridgeport, and finally receives the foul waters of the south fork.

The depth and character of sewage deposits in the river and harbor, as might be expected, vary consider-

ably. They are not great in the track of the vessels, but increase toward the docks and quieter portions of the slips, where they reach a depth of from one to four feet. While the deposits in the channel are of a heavier kind, such as cinders, those in the docks are mostly a foul mass of decomposing organic matter. No form of life is found to exist above Clark street bridge as far north as Clybourn place and as far south as Ashland
502 avenue. The effect of this condition of the river is to endanger the purity of the water supply whenever the river, with its accumulated deposits, flows into the lake, which occurs when the rain water that finds its way into the river exceeds the amount pumped into the canal. If this excess is great, as in the spring and occasionally in the summer months, the contamination of the lake is considerable, and must constantly increase.

From the foregoing it is seen that the present method of disposal of the sewage from Chicago and its suburbs is partly by discharging it into Lake Michigan, but mainly, except during floods, by discharging it into the Des Plaines River.

Future population.

The first question which requires an answer, and upon which many of the subsequent inquiries depended, was the population which it is economical and advisable to consider at present, and the extent of territory upon which such a population will be located.

The growth of Chicago has been frequently quoted as phenomenal. Estimates made thereof for various purposes have turned out to be rather under than over the actual result.

It is taken for granted that Chicago and its suburban towns will have to dispose of their sewage so that the water supply for the entire community residing near the lake from the south line of Hyde Park to the north line of Evanston will be guarded against pollution by the sewage from any one of its separate communities. For this purpose the whole populated area within the above limits is considered as forming one city with a common interest.

The growth of this metropolis was obtained partly from the United States census and partly from the school census of Cook County, which gave a record up to the summer of 1886. In order to forecast the probable ratio of the future increase it was desirable to compare this

growth with that of other cities. By considering the ratio in increase elsewhere, and including the natural suburbs
503 of each city, a fair and instructive basis of comparison was obtained; and by realizing the respective natural advantages for growth in each of the communities the probable ratio for Chicago was determined with a satisfactory degree of exactness.

The accompanying diagram shows the results of this comparison. It represents by curves the population of the largest cities in the country since 1790, not as usually quoted from the census, giving the inhabitants on certain arbitrary areas fixed by law, but as virtually making up the population of the respective municipalities, by including adjacent towns and natural suburbs, the only method which enables the true growth of the great cities to be recognized. For instance, the New York center naturally includes Brooklyn, Jersey City, Hoboken, Newark and other suburbs, and Chicago the entire territory from Hyde Park to Evanston.

The diagram indicates that the character of growth of the different cities permits them to be divided into two distinct classes. Philadelphia, Boston, St. Louis and Cincinnati show very much the same character of increase, and represent by comparison the more conservative communities. New York and Chicago, on the other hand, while showing a remarkable resemblance to each other, form quite a contrast to the rest of the cities, and might be called the more progressive communities. The diagram finally indicates the time when the Chicago curve, which was the lowest one prior to 1864, intersected in turn those of St. Louis, Cincinnati, Boston, and there is a high degree of probablity of its intersecting the Philadelphia curve in or before 1891—*i. e.*, in four years from now—after which Chicago will be the second largest center of population in America.

As it is not practicable in so young a city as Chicago to forecast a definite line of growth, it is preferred to give the probable maximum and the probable minimum between which the true line will most likely be contained. The minimum line represents a growth resembling that of New York and the maximum line assumes the ratio of increase per decade to be consistent instead of gradually decreasing as in most other cities. The result indicates that the population of Chicago and suburbs will be 2,500,000 between the years 1905 and 1915, or about three times the present population is 18 to 28 years.

In providing public works for large communities it
504 must be borne in mind that it is economical to invest only such sums as will bring a return within a certain number of years, leaving expenditures for benefits that will be realized only at a later time to a later generation. This fact, together with the probable growth of Chicago, shows it to be economical and judicious at present to plan works sufficiently extensive to dispose of the sewage of not less than 2,500,000 inhabitants.

In addition to the population the area that will be occupied by it has to be determined. While this is a far more difficult task, owing to the many accidental causes influencing the distribution of the population, it is possible nevertheless to outline the area sufficiently close for the present purposes.

The future metropolis, with a population three times as great, will be distributed along the lake from South Chicago to Evanston, and will reach inland to the Blue Island Ridge on the south to the Des Plaines River in the center, and to the higher parts of Niles Township in the north. Outside of these general limits, a more or less dense population will extend for some distance along the lines of railroad.*

As inferred above, it is proper to consider at this time the wants of the population that will reside upon this entire territory.

Discharge of the Sewage into Lake Michigan.

To discharge the sewage from cities into comparatively large bodies of water is not only the usual, but often the best method for its disposal. Dilution and dispersion thoroughly expose it to the action of the oxygen contained in both the water and the superincumbent air; it is thereby gradually oxidized. Where the body of water is a large river with a strong current, the best conditions for such purification are found. Where it is a lake in which the circulation is slight and irregular, the efficacy of the method is less and depends for its success on the character of the currents and the relative amount of sewage to be discharged into it.

The hydrographic surveys of the lake made during
505 the past season were therefore partly for the purpose of

*Here occurs a diagram showing the "growth of several population centers in the United States," not here reproduced.

ascertaining, if possible, the laws governing the currents, so that we would know their effect in dispersing the sewage discharged into the lake. The trend of the shore currents was actually ascertained by daily recording the direction of spar buoys placed at the Chicago waterworks crib, at Michigan City and at St. Joseph. A large number of bottle floats were thrown into the lake at different points and different times for the same purpose. They were partly single surface floats and partly double, the lower one being placed at varying depths, according to the depth of the water. More than half of them have been picked up and returned, with place and date noted. The currents were also observed by means of large can buoys from an anchored tugboat at different points in the lake, extending from Hyde Park to Evanston, about six miles from the shore. Two general lake trips were undertaken, one to St. Joseph and back to Grosse Point, and another one parallel with the shore around the head of the lake.

When the observations are completed and compiled in detail, some valuable information will be available for the question of water supply. Light will be thrown on the movement of the water under different winds and the sudden changes of temperature of the water at the crib and on the turbidness of the same.

The following results have a bearing on the question of sewage disposal: Where not affected by local conditions, the currents practically go with the winds in water of moderate depth and quickly respond to any change. In deep water also the surface currents run with the wind, but at the bottom and even at mid-depth the direction is usually different. The prevailing current along the shore of Cook County during the past summer has been observed to be toward the north, but it is possible that this result may be different during the winter months. In the open lake wave action seems to be effective in preventing the permanent deposits down to a depth of about 60 feet; inside of the breakwater sewage deposits are found on the bottom.

The general deduction from these results is clear that, as no constant current exists which would carry the sewage away in one direction, it should be discharged into the lake at one end of the future city, while the water supply should be obtained as far away from it as prac-
506 ticable towards the other end, a conclusion which is being acted upon in the other large lake cities. The proper place from which to bring the water would be opposite

Grosse Point, and the sewage discharge should be east of Hyde Park. While it might be practicable to allow the sewage in its crude form to enter the lake under such conditions for many years, the necessity would arise later for clarifying it at least partially previous to its discharge. It could not be allowed to run into the river as at present, but the dry weather flow and a considerable amount of storm water would have to be intercepted and carried to the outfall through many miles of special conduits. This entire quantity would have to be raised by pumping in order to get sufficient head to empty into the lake, while the diluted sewage during storms, in excess of the capacity of the intercepting sewers, would be allowed to discharge directly into the river.

The water supply would have to be brought from Grosse Point in large conduits to the several pumping stations scattered over the city and its present suburbs. The circulation of the water in the Chicago River and branches would have to be maintained practically as it is at present, because the removal merely of the dry weather flow of sewage would not altogether prevent is pollution.

Disposal on land.

We shall not at this time enter into a general discussion of the principles underlying land purification of sewage, or make historical references showing the success or ill success of the method as practiced elsewhere. We will simply state that with good management under ordinarily favorable conditions a disposal on land proves satisfactory, so far as the purification of the sewage is concerned, and that with proper conditions in the way of good markets and a favorable soil and climate sewage farms can be operated on a large scale after the sewage is delivered upon the same without financial loss.

In speaking of a sewage farm of the magnitude required for the metropolitan area of Chicago, it is not understood as being land devoted primarily to the raising of crops, using the sewage only when and where it
507 would most promote the growth of vegetation. The primary object would be the purification of the sewage on an area of land as small as could serve the purpose. Technically speaking, the sewage disposal would be by means of intermittent filtration rather than irrigation. To carry out such a scheme for Chicago involves the following:

(1) The acquirement of sufficient land suitable for the purpose.

(2) A comprehensive system of intercepting and collecting sewers carrying the sewage to the farm.

(3) Pumping works of a capacity to handle all the dry weather flow of sewage and a certain proportion of storm water.

(4) A thorough underdrainage, leveling and preparing of beds for the filtration areas.

(5) A system of underground conduits and surface carriers for distributing the sewage over the ground and a system of open ditches for removing the purified water to the nearest water courses.

(6) Buildings, roads, and a complete farming outfit.

(7) An organization for properly distributing the sewage, for carrying on the farming operations, for conducting the business of disposing of the crops in the best market.

In making estimates for the size of intercepting sewers, conduits, pumps and area of land required, we have used as a basis a population of 2,500,000 people, with an average dry weather sewage discharge of 150 gallons, or 20 cubic feet, per head daily, and made provision for storm water equivalent to one-fifth of an inch in 24 hours over all portions of the district now drained or likely to be drained by a combined system of sewers, allowing surplus water to escape in the rivers and lakes.

The dry weather flow of sewage would therefore be 50,000,000 cubic feet per day, and the maximum flow of storm water 65,000,000 cubic feet per day, making a total maximum discharge of 115,000,000 cubic feet.

From an examination of rainfall tables we conclude that the annual amount of storm water that would be carried off by such an intercepting system would range from 9 to 12 inches, an average of which in round numbers may be taken at 40,000 cubic feet per acre per annum over the area drained by a combined system of sewers. It is practicable, however, to exclude the storm water from the sewers over a large portion of the future
508 city by adopting the separate system of sewerage. The area north of the town of Jefferson and of the middle of Lake View may be treated to advantage in this way,

and also a large portion of Hyde Park, Lake Calumet and other adjacent towns.

Assuming that the area which does not allow the storm water to be entirely excluded is 140 square miles, the average daily amount becomes 10,000,000 cubic feet, which gives, when added to the sewage, 60,000,000 cubic feet, or 24 cubic feet per head of population per day to be provided for on the farm.

As the amount of land required to purify sewage can only be determined by experience, and as this has been very limited in our own country, we are forced to rely mainly upon that of Europe. Without going into details at present, we will simply state that a fair consensus of this experience justifies us in the conclusion that from 10,000 to 15,000 acres of land would be required to dispose of the sewage from the entire metropolitan area.

The only available territory for sewage filtration in the neighborhood of Chicago consists of two sandy ridges in the Town of Thornton, extending across the state line into Indiana, and in a sandy ridge crossing the Town of Niles. The soil is quite favorable, but the character of the surface is such that the necessary preparation to make it suitable for filtration beds would be comparatively expensive. An enormous cost is, however, represented by the fact that the sewage would have to be collected by large intercepting sewers, lifted altogether some 90 feet, and carried about 20 miles before reaching the farms. We therefore consider such a project entirely impracticable.

The land treatment can only be seriously thought of in connection with the sewage disposal from the smaller areas mentioned above and comprising the extreme northern and southern parts of the future metropolis. The drainage of parts of Evanston, Lake View and Niles might be taken to the sandy ground in the latter town, and that of the Calumet region to the sandy ridges in Thornton, should this method be found most advantageous when compared with others.

The preliminary investigation made for this purpose consisted in an examination of the grounds in the projection of a farm, and in an estimate of the cost of preparing the same and delivering the sewage to it by intercepting sewers and conduits.

Discharge of the Sewage into the Des Plaines River.

509 [A third solution of the drainage problem is rendered practicable by the fact that the divide between Lake Michigan and the Mississippi Valley lies about 10 miles west of Chicago, with so slight an elevation that it is not a difficult matter to carry the sewage from the city westward into the Des Plaines River, and thence into the Mississippi River.] The method of disposal, as previously explained, is in fact mainly the present one, most of the sewage now being carried across the divide by the Illinois and Michigan Canal.

There are two low depressions between the future metropolis and the Des Plaines River—the Mud Lake Valley, with the present canal, and the Sag Valley west of Lake Calumet. Neither is more than 10 feet above the lake, nor do they present any engineering difficulties for canal construction. It is therefore quite feasible to carry all the drainage from the territory ultimately to be occupied by the metropolis, extending from Lake Calumet to Evanston, into the Mississippi Valley through these depressions, avoiding thereby all possible lake pollution and permitting the supply of water to be drawn from any number of convenient points in front of the city.

The possibility of this solution was recognized as early as 1856 by Mr. E. S. Chesbrough, and the first step towards its adoption was taken, as already mentioned, by turning the sewage into the Illinois and Michigan Canal. Not until quite recently, however, has it become practicable to consider the construction of a special waterway for sewage removal, because when the population was smaller the expense of the undertaking was too great.

The sanitary requirements demand a flow of water large enough to dilute sewage sufficiently to make it inoffensive along the river at all times. Beyond this, any increase in the size of the channel to provide for the storm water which naturally enters it should be kept at a minimum. A glance at the map and an examination of the ground show the possibility of diverting the greater part of the storm water from the metropolitan district without serious difficulty. Both branches of the Calumet River can be diverted west of the Indiana state line into Wolf Lake, and thence into Lake Michigan. The Des
510 Plaines River can have its flood water diverted into the North Branch near the north line of the Town of Jefferson, and the combined waters can be led from Bowmanville directly into the lake. Salt Creek, a branch of the

Des Plaines River, can readily be turned southwardly near Western Springs, through a water course known as Flag Creek, at one time evidently its old bed, discharging into the Des Plaines opposite Sag, and thus reducing the necessary storm water capacity in the new channel between Sag and Summit.

In order to determine the probable quantity of flood water which can thus be excluded, it was necessary to ascertain the maximum flood discharges from all the watersheds in question. This requirement called for a gauging of Des Plaines, North Branch and Calumet Rivers; a gauging of the rainfall, which is a measure of the stream flow; a survey of the watersheds and an examination of the river channels. It was also necessary to make a reconnoissance of all possible lines for diverting the Des Plaines, the North Branch, the Calumet River and Salt Creek, and a survey of those which were most important.

The results indicate that each one of these diversions is both practical and economical. By adopting the "separate system" of sewerage for the territory lying north of the proposed Bowmanville channel, the surface drainage from this territory can be safely turned into the lake.

A second branch of the investigation extends to the elements governing the proper size of the waterway from which a large proportion of the storm water has been excluded. The area still draining into it will consist largely of paved streets and roofs, allowing of no absorption and shedding the water rapidly. It requires a careful consideration to determine the maximum quantity of water that may enter the proposed channel, and for which an ample allowance must be made to prevent a back flow of the polluted water to the lake.

The proper degree of sewage pollution in the new channel demanded a careful investigation. When sewage is mingled with a sufficiently large quantity of water it not only becomes inoffensive, but readily finds the oxygen which gradually purifies it. When the surface is covered with ice a greater dilution is necessary for this purpose than at other times when there is a constant
511 replenishment of oxygen from the air. The proposed waterway should, of course, provide immunity from offense at all times.

The information upon which definitely to decide this question will be given in the final report, as the data have not yet been all collected, owing to the necessity of

making actual tests of the oxidation of the canal water under the ice, which is being done for the use of the commission by Dr. J. H. Rauch, secretary of the State Board of Health. The summer conditions are presented in his late report on the water supply and sewage disposal of Chicago. The result of these analyses will be compared with those of other streams that are also polluted with sewage in order to show the rate of oxidation with varying degrees of dilution and aeration.

For the purpose of estimating the cost of the water channel we have assumed 3,600 square feet for the cross section and a velocity of the water 3 feet per second, or 2 miles per hour. This gives a discharge of 600,000 cubic feet of water per minute, or 24,000 cubic feet for each 100,000 persons, which we believe equal to the maximum requirements of a population of 2,500,000 people.

A third branch of the inquiry covers the selection of routes for the proposed canals.

Between Chicago and Summit three lines are practicable—one following the west fork and Ogden ditch, and another extending from the southwestern end of the south fork in a westerly direction to the Ogden ditch, and thence to Summit, and a third being an enlargement of the present canal. We are of the opinion that eventually both the first and second of these lines should be adopted, but that the second one should be built first in order to secure circulation in the south fork. From Summit westward the bed of the river and the present canal were the only lines to be considered. The best location has not yet been finally determined.

For the drainage of the Calumet region a simple inspection shows that a canal should start from the river at the southern point of Blue Island, and extend almost directly westward to the Des Plaines Valley at Sag.

A fourth branch of the inquiry relates to the study of such data as have reference to securing a proper circulation for the waterways within the city.

To throw light upon this point the variations of the lake level have been recorded since last spring by means
512 of an automatic gauge indicating an almost continual fluctuation, averaging several inches, and recurring at periods of about 20 minutes. During a low pressure of the atmosphere the amplitude of these oscillations increases, and not unfrequently reaches several feet. The accompanying diagram shows the level of the lake on

August 16, 1886, at a time when an area of low barometer passed over it. From 6:40 a. m. to 6:55 a. m.—that is, in 15 minutes—the water fell 2 feet 10 inches.

A rising level causes an inflow to the river and drives the water of the latter into the slips, where it deposits a portion of its suspended sewage matter and becomes foul. A falling level reverses the flow, and the slips empty their foul water into the river and lake. During heavy fluctuations of the latter, such as the one referred to above, it has been traced more than a mile in the direction of the crib.

As the proposed canal from Bowmanville to the lake will lower the water of the North Branch at this point to the lake level, provision must be made for its circulation. The size of the Fullerton avenue conduit is not sufficient to furnish the water required for a current in both directions, nor would such an arrangement be satisfactory or economical. It will be necessary to establish a flow towards the South Branch from the lake opposite Bowmanville in order to prevent a future lake pollution by the proposed channel. This can be accomplished by placing a lock in the North Branch at any point that may be found most desirable and raising the water at the same time about one foot. If such a lock is placed at Fullerton avenue the present pumping works, with slight modifications, can be utilized.

Finally, it must be mentioned that circulation can be secured in the proposed waterways of the Calumet region, into which the sewage is discharged, by a gravity flow from Lake Michigan into the Des Plaines Valley through Lake Calumet and the Sag. The detailed features of this project have not yet been wholly matured, the estimates of cost being based on a channel having a capacity of 1,000 cubic feet per second.

Comparison of projects.

513 In the foregoing we have outlined the main features of the only three feasible methods of disposing of the metropolitan sewage, and have given the results of the investigation reached to date. A general conclusion as to the preferable method may be given at present, and also an approximate estimate of cost. But we are not able as yet to give either conclusions or detailed statements of the probable expense regarding all parts of the

proposed work, and must defer them until the final report.

In comparing the projects we will first mention their probable cost and then their relative advantages.

The discharge of the sewage into the lake from a population of 2,500,000 in the manner described above, including the extra expense, otherwise not necessary, of taking the water supply of Grosse Point, would cost at least $37,000,000, with an annual expense for interest and operation of at least $2,400,000. It would require an immediate investment of about $20,000,000.

To dispose of the entire metropolitan sewage by filtration on land would require an investment of about $58,000,000, with an annual expense of over $3,000,000 for interest, pumping, and maintenance, after deducting the profit from the sale of crops. It would be necessary to invest at once about $34,000,000. Land disposal for the sewage, from the Calumet region alone, with a future population of 300,000, would require an investment of about $4,000,000 and an annual expense of at least $250,000.

Finally, the cost of the Des Plaines project is approximately estimated as follows:

1. A channel from the South Fork to Joliet of the capacity heretofore given will cost between $17,000,000 and $21,000,000.

2. A diversion of the flood waters of the Des Plaines, the North Branch, and Salt Creek will cost between $2,500,000 and $2,800,000.

3. Pumping works and locks for the North Branch will cost about $150,000.

Omitted; printed in House Ex. Doc. No. 264, 51st Cong., 1st sess.

514 4. A separate system of sewers to collect the sewage now discharged directly into the lake and to carry it into the river will cost about $600,000.

5. A channel from Lake Calumet to Sag will cost between $2,500,000 and $3,000,000.

6. A diversion of the flood waters of the Calumet River will cost between $350,000 and $400,000.

The total cost of the Des Plaines drainage project would therefore be, for the main district, between $20,250,000 and $24,550,000; for theCalumet district, between $2,850,000 and $3,400,000. The annual cost, including interest, etc., is estimated at about $1,300,000 per annum.

The pollution of the lake can be decreased and the present condition of the Chicago River, and particularly of the South Fork, can be improved by the immediate construction of the following works, which, with the exception of the pumping works at the South Fork discharging into the Illinois and Michigan Canal, are all a part of the final plan.

1. Channels diverting the flood waters of the Des Plaines, North Branch, and Salt Creek, as described above.

2. A modification of the Fullerton avenue pumping station and the construction of locks for the purpose of getting circulation in the North Branch.

3. A separate system of sewers to collect the sewage now flowing into the lake from the south division and to discharge it into the South Fork.

4. A waterway extending from the western end of the South Fork to the Illinois and Michigan Canal, with a new pumping station to promote circulation.

5. By raising the banks of the canal and by removing deposits this capacity can be increased 40 per cent. at a small cost, and thus provide for a greater flow of water in the same.

The cost of the works comprised under these five items is estimated to be between $5,000,000 and $5,500,000. They could be finished in three years, and would greatly lessen the liability of polluting the water supply, while the sewage would be disposed of in the best practicable maner until the final completion of the Des Plaines project.

It therefore appears that this project is decidedly the least expensive one for the present as well as for the future.

Besides the economical advantages of the Des Plaines scheme, its superiority is still further emphasized by advantages of another kind. The proposed canal will, from
515 its necessary dimensions and its regular discharge, produce a magnificent waterway between Chicago and the

Mississippi River, suitable for navigation of boats having as much as 2,000 tons burden. It will establish an available water power between Lockport and Marseilles fully twice as large as that of the Mississippi River at Minneapolis, which will be of great commercial value to the state. The Calumet region will be much enhanced in value by having a direct navigable channel to the Des Plaines River and by a lowering of the flood heights of Calumet Lake and River. Within the city the water of the Chicago River and its South Branch will get a much better circulation if it flows by gravity than if it has to be pumped, the necessity for which would remain even if the sewage should be discharged through intercepting sewers, either into the lake or upon land. Upon either of the latter conditions an occasional overflow from the sewers into the river during heavy rains would be more objectionable than a constant discharge of sewage into a more rapidly flowing stream. Flood waters entering the lake by way of the Chicago River would carry into it much filthy matter, either suspended or deposited, notwithstanding the existence of intercepting sewers, but the proposed diversion of such waters before reaching the populated districts will for all time obviate this undesirable occurrence. Lowering the level of the North Branch at Bowmanville by its diversion to the lake will be equivalent to raising the low prairie extending towards Evanston and Niles and greatly benefit parts of these towns.

The water supply.

In reaching the conclusion that the sewage of the city should be discharged into the Mississippi Valley the question of water supply is materially simplified, because the lake will then at all times furnish good water wherever intakes are desired for an extension of the works."

The Illinois General Assembly in 1887 did not pass the Sanitary District Act known as the Hurd Bill but authorized a joint committee to sit *ad interim* and report to the next session of General Assembly in 1889. See testimony of Cooley (Rec. Vol. III, p. 1727. This narrative p. 280.)

In a report by Major W. H. H. Benyaurd, under the Rivers and Harbors Act of August 2, 1882, (Rec. Vol. IV, p. 2251), he said:

"EXTRACT FROM THE CHIEF OF ENGINEER'S REPORT 1884, APPENDIX HH, P. 1957, ENTITLED 'PRELIMINARY EXAMINATION OF ILLINOIS AND DES PLAINES RIVERS BETWEEN LA SALLE AND JOLIET, ILLINOIS.'

UNITED STATES ENGINEER OFFICE,

CHICAGO, ILL., September 2, 1882.

General: I have the honor to present the following report in regard to the proposed survey of the Illinois and Des Plaines Rivers from Joilet to La Salle, Ill., as provided for in the river and harbor act of August 2, and assigned to my charge by letter of August 11.

Several surveys have been made of the route by the State and by the General Government, and I have not deemed it necessary therefore to make a personal examination of the stretch of river in question, in order to report upon the necessity of an instrumental survey. I have examined the maps and consulted the reports and other sources of information, and deem it necessary to make survey, estimates for which are presented herewith.

The necessity of the improvement derives its importance from several considerations. The State has improved the river for ship navigation from La Salle to Copperas Creek, and the Government is now engaged in
2252 continuing the improvement thence to the mouth. I am directed to report upon the cost of enlarging the Illinois and Michigan Canal, which extends from Lake Michigan to La Salle. This work, if ever carried on, will give through navigation for large vessels from the lake to the Mississippi. The canal runs in close proximity to the river the entire distance from Joilet to La Salle, and in making up the estimates for the enlargement of the canal it will be necessary to discuss whether or not it will be more economical to enlarge the canal between those two points, or to improve the river and abandon the other.

Very respectfully, your obedient servant,

W. H. H. BENYAURD.
Major of Engineers.

Brig. Gen. H. G. Wright,
Chief of Engineers, U. S. A."

March 5, 1884, Major Benyaurd made a further report pursuant to said Act of August 2, 1882, in which it was stated:

> "That with the improvement of the River now in question carried on, navigation will be brought to within thirty-three miles of the Lake, and this stretch can be opened by improving the DesPlaines higher up and by enlarging the present Illinois and Michigan Canal."

Section 4 of the Rivers and Harbors Act of August 5, 1886, is as follows:

> "Sec. 4. The Secretary of War shall prescribe such rules and regulations as may be necessary to secure a judicious and economical expenditure of the money herein appropriated, and shall cause to be made and submitted to Congress annual reports, together with maps and plans, including the report of the Mississippi River Commission, on or before December first, giving detailed statements of the work done, contracts made, the expenditures thereunder or otherwise, and balances of money on hand up to November first, and the effect of such work, together with such recommendations as he may deem proper. He shall at the same time report to Congress all cases in which piers, breakwaters, locks and dams, or other structures or works built or made by the United States in aid of commerce or navigation are used, occupied, or injured by a corporation or an individual, and the extent and mode of such use, occupation or injury. He shall report, at the same time, whether any bridges, causeways or structures now erected or in process of erection do or will interfere with free and safe navigation."

In a report by Major Handbury, 1887, under the Rivers and Harbors Act of August 5, 1886, (Rec. Vol. IV, p. 2257) he said:

> "Extract from a Report of Major Handbury, Chief of Engineer Reports 1887, Appendix II, p. 2119, Entitled 'Improvement of Illinois River, Illinois.'
>
> The project now in the course of execution for the reach of the Illinois River lying between the state lock at Copperats Creek and the mouth, a distance of 135 miles, contemplates the construction of two locks and dams and the dredging of a channelway where neces-

sary, so as to insure a continuous depth throughout of not less than 7 feet at low water.

The sites selected for the locks and dams are one at Kampsville, about 30 miles above the mouth of the river: the other at LaGrange, 45 miles above Kampsville. These locks are 350 feet long and 75 feet wide, with 7 feet over miter-sills at low water.

The ultimate object of this improvement is to provide a channelway from the lower end of Lake Michigan to the Mississippi River of sufficient capacity to accommodate large sized Mississippi River boats, so that the products of the country may be carried from the Lake to the Gulf without breaking bulk; also to enable vessels of war of considerable capacity to pass freely from the Gulf of Mexico into the defenseless waters of our northern lakes, should the exigencies of our foreign relations ever require this to be done.

Page 2121.

When this work is completed it will then be practicable for the large steamers belonging to the Upper and Lower Mississippi, the Ohio, and Missouri Rivers to come with their unbroken cargoes to within 100 miles of Lake Mich-
2258 igan. All this can be brought about by an expenditure on the part of the government of less than $600,000.

The Illinois River, from the western terminus of the Illinois and Michigan Canal at LaSalle to Copperas Creek, about 80 miles below, has been improved by the State of Illinois by means of two locks and dams similar to those in process of construction by the United States on the river below. From LaSalle to Joliet the Illinois and Des Plaines Rivers have been carefully surveyed, and plans and estimates of cost for their improvement to the same navigable capacity as the river below have been made and submitted to Congress. The report on this project submitted by Maj. W. H. H. Benyuard, Corps of Engineers, U. S. Army, may be found in the Chief of Engineer's Report for 1884, page 1958. The estimated cost of improving this reach of the river is $3,433,562. The distance is 64 miles and the fall 100 feet. Congress has now before it the engineering data showing the feasibility and cost of a water communication between the Mississippi River and a point 30 miles distant from navigable water leading into Lake Michigan sufficiently commodious for the commercial and military exigencies of

the country, and from this point to the lake perfectly practical routes over which the line can be constructed are known to exist. It only remains for Congress to provide the means for making the necessary surveys and estimates of cost for continuing this work from Joliet to Lake Michigan, when it will have the engineering features of the whole subject before it in a shape necessary for intelligent legislation. I estimate that about $10,000 will be sufficient to defray the expenses of the necessary surveys and examinations and preparation of the plans and estimates of costs of the work.

The United States and the State of Illinois have long been committed to the project of opening a water communication between the Mississippi River and the north-
2258 ern lakes of capacity sufficient for the wants of commerce and for the exigencies of our national defense, should these ever arise. The amount expended by the United States to the end of the present fiscal year in carrying out this project is $680,633.42, exclusive of $62,359.80 expended on the foundation of the Copperas Creek Lock, which was afterwards turned over to the State. The cost of the locks and dams built by the State of Illinois at Copperas Creek and Henry was $747,747.

The distance by this route from the Gulf of Mexico to the southern end of Lake Michigan is about 1,620 miles. When the projected improvement of the Illinois
2259 River below Copperas Creek, on which we are now working, has been finished, more than 1,520 miles of this distance will be available for the water transportation of commerce in bulk between these points. Pushing this improvement through to the lake, the connecting line will be formed which will join the northern lakes with the vast net-work of navigable rivers whose waters flow into the Gulf of Mexico on a scale to a certain degree commensurate with the importance of the commerce that will be affected by it. The mere fact that such a route is available will serve as a wholesome regulator to the rates that would be exacted by other methods of transportation were this one not in existence. Besides the immense commercial advantages that may be expected from the completion of the project, there are military and naval exigencies that might easily arise where it would figure as a prominent factor in the problem of our national defenses. From whatever point we look at the subject there is nothing local or sectional in it. It is true that all the work to be done happens to be in

the State of Illinois. The benefits to be derived belong to the nation at large. It is fortunate, too, that at this time the subject is unencumbered by any phase of a political character. The problem of connecting Lake Michigan with the Mississippi River by a commodious waterway, that could be used for commercial, military and naval purposes, has received attention from our most thoughtful statesmen from the day of Albert Gallatin to the present."

On May 28, 1889, the legislature of the State of Illinois passed a resolution stating the deep waterway policy of the state asking the cooperation of the Federal Government for the construction of the Sanitary District Channel. The Resolution is as follows (Rec. Vol. IV. pp. 2329-30):

"Joint Resolution

Whereas the present addition to the low-water volume of the Illinois River through the summit level of the Illinois and Michigan Canal from Lake Michigan more than doubles the volume of water used in the estimate of 1868 for the channel below Peru, and adds 50 per cent to the volume used in the estimate of 1880 for the channel below Copperas Creek and said contribution from Lake Michigan will be increased in the immediate future, thus enabling the depth now projected for navigation below Peru to be obtained by channel improvement at moderate cost, and with decided advantage to material interests and to healthfulness along the valley.

Whereas it is contemplated to increase the volume from Lake Michigan to 300,000 cubic feet per minute within a few years, and ultimately to add 600,000 cubic feet or more, thus enabling a large depth for navigation to be obtained by an improved channel, and that said channel will be self-sustaining and self-improving and will discharge flood waters more readily, thus benefiting the bordering lands and increasing the healthfulness of the valleys.

Whereas works now projected by the City of Chicago will form part of a waterway of large proportions from Lake Michigan via the Des Plaines and Illinois rivers to the Mississippi River, of which the dams and locks upon the alluvial section of the Illinois River, can form no part, and which, if allowed to remain, will increase,

overflow and be detrimental to the welfare of the Illinois Valley and the interests of the State: Therefore be it Resolved,

By the Senate of the House of Representatives concurring herein (1) That it is the policy of the State of Illinois to procure the construction of a waterway of the greatest practicable depth and usefulness for navigation from Lake Michigan via the Des Plaines and Illinois rivers to the Mississippi River and to encourage the construction of feeders thereto of like proportions and usefulness. (2) That the United States is hereby requested to stop work upon the locks and dams at La Grange and at Kampsville, and to apply all funds available and future appropriations to the improvement of the channel from La Salle to the mouth with a view to such a depth as will be of present utility and in such manner as to develop progressively all the depth practicable by the aid of a large water supply from Lake Michigan at Chicago. (3) That the United States is requested to aid in the construction of a channel not less than 160 feet wide and 22 feet deep with such a grade as to give
2230 a velocity of 3 miles per hour from Lake Michigan at Chicago to Lake Joliet, a pool of the Des Plaines river, immediately below Joliet, and to project a channel of similar capacity and not less than 14 feet deep from Lake Joliet to La Salle all to be designed in such manner as to permit future development to a greater capacity.

On May 29, 1889, the Legislature of the State of Illinois passed an act providing for the creation of the Sanitary District of Chicago, which act became in force, July 1, 1889. (Rec. Vol. VIII, p. 92.) Said Act provides for the size of channel to be constructed in Section 23. (Rec. Vol. VIII. pp. 103-104.) Other sections of the Act are set forth in this narrative statement page 69.

"23. If any channel is constructed under the provisions hereof by means of which any of the waters of Lake Michigan shall be caused to pass into the Des Plaines or Illinois river such channel shall be constructed of sufficient size and capacity to produce and maintain at all times a continuous flow of not less than 300,000 cubic feet of water per minute, and to be of a depth of not less than fourteen feet, and a current not exceeding three miles per hour, and if any portion of any

such channel shall be cut through a territory with a rocky stratum where such rocky stratum is above a grade sufficient to produce a depth of water from Lake Michigan, of not less than eighteen feet, such portion of said channel shall have double the flowing capacity above provided for and a width of not less than one hundred and sixty feet at the bottom capable of producing a depth of not less than eighteen feet of water. If the population of the district draining into such channel shall at any time exceed 1,500,000 such channel shall be made and kept of such size and in such condition that it will produce and maintain at all times a continuous flow of not less than 20,000 cubic feet of water per minute for each 100,000 of the population of such district, at a current of not more than three miles per hour, and if at any time the general government shall improve the Des Plaines or Illinois rivers, so that the same shall be capable of receiving a flow of 600,000 cubic feet of water per minute, or more, from said channel, and shall provide for the payment of all damages which any extra flow above 300,000 cubic feet of water per minute from such channel may cause to private property so as to save harmless the said district from all liability therefrom, then such sanitary district shall within one year thereafter, enlarge the entire channel leading into said Des Plaines or Illinois rivers from said district to a sufficient size and capacity to produce and maintain a continuous flow throughout the same of not less than 600,000 cubic feet of water per minute with a current of not more than three miles per hour, and such channel shall be constructed upon such grade as to be capable of producing a depth of water not less than eighteen feet throughout said channel, and shall have a width of not less than one hundred and sixty feet at the bottom. In case a channel is constructed in the Des Plaines river as contemplated in this section it shall be carried down the slope between Lockport and Joliet to the pool commonly known as the upper basin of sufficient width and depth to carry off the water the channel shall bring down from above. The district constructing a channel to carry water from Lake Michigan of any amount authorized by this act, may correct, modify and remove obstructions in the Des Plaines and Illinois rivers wherever it shall be necessary so to do to prevent overflow or damage, along said river, and shall remove the dams at Henry and Copperas Creek in the Illinois river, before any water shall be turned into the said channel. And the canal commissioners, if they shall find at any time that an additional

supply of water has been added to either of said rivers, by any drainage district or districts, to maintain a depth of not less than six feet from any dam owned by the State, to and into the first lock of the Illinois and Michigan Canal at La Salle, without the aid of any such dam, at low water, then it shall be the duty of said canal commissioners to cause such dam or dams to be removed."

In the report of Captain Marshall, United States Engineer at Chicago of February 28, 1890, Captain Marshall (Rec. Vol. IV, pp. 2156-58) said: Chief of Engineers Reports 1890 Appendix J. J. 2419.

Survey of Waterway from Lake Michigan to the Illinois River at La Salle, Illinois.

"United States Engineer Office.

Chicago, Ill., February 28, 1890.

General: I have the honor to submit the following report upon a survey of a waterway from Lake Michigan to the Illinois River at La Salle, Ill., forming part of a through route of transportation from Lake Michigan to the Mississippi River, required by Act of Congress of August 11, 1888.

2157 The Act in question is entitled 'An Act making appropriations for the construction, repair, and preservation of certain public works on rivers and harbors, and for other purposes,' and the items directing the survey, plans and estimates, and relating thereto, are as follows:

'Improving Illinois River, Illinois: Continuing improvement Two Hundred Thousand Dollars. And for the purpose of securing a continuous navigable waterway between Lake Michigan and the Mississippi River, having capacity and facilities adequate for the passage of the largest Mississippi River steamboats, and of naval vessels suitable for defense in time of war, the Secretary of War is authorized and directed to cause to be made the proper surveys, plans, and estimates for a channel improvement and locks and dams in the beds of the Illinois and Des Plaines Rivers from La Salle to Lockport, so as to provide a navigable waterway, not less than one hundred and sixty feet wide, and not less than fourteen feet deep, and to have surveyed and located a channel

from Lockport to Lake Michigan, at or near the City of Chicago, such channel to be suitable for the purposes aforesaid; the necessary expenses of such surveys, estimates, plans and location to be paid for out of the sum herein appropriated for the improvement of the Illinois River.'

In compliance with the orders of the Chief of Engineers a project for this survey was submitted September 21, 1888, which was approved September 25, 1888. The expenses of the survey to be paid from an allotment of $25,000 from the appropriation for the improvement of the Illinois River.

A letter of instructions was received from the chief of engineers, dated August 27, 1888, a copy of which is herewith, directing that whatever line might be found most advantageous and economical to the United States, and best suited to subserve the ends in view, that plans and estimates in any event should be submitted for a route terminating within the (then) limits of the City of Chicago sufficiently distinct and in detail to enable the Chief of Engineers to form a definite and conclusive
2158 opinion as to its merits regarded from the standpoint of the commercial and sanitary interests of Chicago.

The most practicable routes across the Chicago Divide, and which have been long known and recognized, are two, each of which admits choice of location, the valleys being quite wide.

(1) By way of the Chicago River and its South Branch and the present location of the Illinois and Michigan Canal, or Mud Lake and the Ogden Ditch, to the Des Plaines, near Summit, about 12 miles from the City Hall of Chicago and about 8 miles from Bridgeport; thence via the Des Plaines River Valley, uniting at Sag Bridge with route."

* * * *

Referring to the drainage and water supply commission report of 1887 and the Sanitary District Act of 1889, the United States Engineer reports to the Chief Engineer as follows: (Rec. Vol. IV, 2161, 2162, 2167.) (Chief of Engineers Report 1890 Appendix J. J. 2436.)

2161 "Page 2436.

Attached to this report will be found the full preliminary report of the special commission or board of experts employed by the City of Chicago to examine into the question of drainage and water supply, made in 1887; also the laws and joint resolutions of the Legislature of the State of Illinois relating to the same matter, and authorizing the establishment of 'Sanitary Districts, etc.,' which will give a clear explanation of the requirements of the case and the proposed remedies.

Without going into the subject in detail, which is better treated in the report mentioned than it could be by me, it is sufficient to state that after examination by capable experts the conclusion has been arrived at that it is necessary, for sanitary reasons, to construct a channel or channels from the lake to the Des Plaines valley, beyond the Chicago Divide, capable of carrying to the Illinois River from 300,000 to 600,000 cubic feet of water per minute, to carry off and dilute to inoffensiveness the sewage of
2162 this great city, to prevent contamination of its water-supply *necessarily taken from Lake Michigan;* and that the necessary legislation to enable the city to undertake the work has been obtained from the State Legislature.

2167 Commercial Advantages.

This route has invited attention as a practicable locus for a waterway between the Great Lakes and Mississippi River for many years, and its advantages have been so often reported to Congress that anything herein said would be more repetition. It is sufficient to say that the minimum channel herein estimated upon will open a channel of commerce with a maximum annual capacity of 30,000,000 tons (foot note: Or 7,500,000 tons easily attainable capacity in practice.—W. L. M.) between the Great Lakes, with its terminus at their greatest port, and a system of navigable rivers penetrating one-half of the states and territories of the Union, with a total navigable length equal to more than half the circumference of the globe."

On April 21, 1891, the Sanitary District of Chicago passed a resolution for improving the Chicago River, which resolution is as follows (Rec. Vol. IV, pp. 2274, 2275):

"Resolution of April 21, 1891, of the Board of Trustees of the Sanitary District of Chicago.

Resolved, That this Board hereby ordains that The Sanitary District of Chicago do forthwith enter upon, use, widen, deepen and improve the Chicago River from its mouth at Lake Michigan to the South Branch thereof, and also the South Branch thereof, together with the South and West Forks thereof so as to make the same a proper and sufficient supply channel for the main channel heretofore surveyed from the Chicago River to Joliet; and further, that the Acting Chief Engineer be, and he is hereby, directed immediately to investigate and report upon the capacity of said River and its said South Branch and Forks for that purpose, and also as to any changes that should be made therein, and that a copy of this resolution, certified by the clerk, be forthwith transmitted to the Mayor and Common Council of the City of Chicago, and the Secretary of War of the United States."

In 1892 the United States Engineer at Chicago, Captain Marshall in a report to the Chief of Engineers, United States Army, reported the progress of the work of the Sanitary District as follows, Chief of Engineers Report 1892, Appendix J. J., page 2255 (Rec. Vol. IV, pp. 2180-2182):

"Page 2258.

The completion of the La Grange Lock and Dam has been followed by a material increase in the tonnage passing La Grange. The completion of the Kampsville Lock
2181 and the dredging the channel below it by extending the period of navigation there will have a more marked effect still in increasing the size and tonnage of vessels navigating the Illinois River and the value of this stream as a means of transportation.

Doubtless the slow improvement of this river has resulted from a difference of opinion as to the method of improvement that should be applied: On the one hand, the necessities of the city of Chicago for better drain-

age has demanded a large discharge into the Illinois River for sanitary purposes, which discharge would make an open river improvement practicable below La-Salle; on the other hand is the fact that the most economical and effective system, as far as navigation is concerned, is that by slackwater, modified, perhaps, by movable dams in the alluvial valley of the Illinois, Lake Michigan being the summit level, the channels being comparatively shallow but of greater width than proposed for sanitary purposes. Additional friction and consequent injury to both the scheme for a navigable channel and to the local drainage measure, delaying both, has been due to the demand by advocates of the latter that the United States shall construct the navigable channel of the dimensions necessary for the drainage scheme, without regard to the most economical channel and speedy method of meeting the absolute requirements of commerce by water over the connecting link between 14,000 miles of interior navigation existing upon the Mississippi River and its tributaries, and the Great Lakes.

These dissensions are now apparently quieted, and without friction the question of the extension of the navigation existing on the Western rivers to the Great Lakes, the best dimensions and location of channel from Joliet to La Salle, and the advisability and conditions of joint use by the United States for navigation and the city of Chicago for drainage of the channel that must be cut for both purposes across the rock in place, from near Willow Springs to near Lockport, can be now examined.

Upon this subject the reports of the Chief of Engineers for 1889, page 2121, *et seq.;* for 1890, page 2419, *et seq.;* and 1891, page 2611, *et seq.,* are referred to.

The authorities of the sanitary district of Chicago have progressed so far with their work as to have definitely located for the third time a part of the drainage channel, and have taken an additional step in advance by soliciting and receiving proposals for the construction of their channel for drainage across the rock between
2182 Willow Springs and Lockport. The prices secured are very favorable; the contract has not yet been awarded, but the proposals are under advisement by the trustees."

On August 9, 1893, Captain Marshall, United States Engineer at Chicago made a report to the Chief of Engineers which was by him transmitted to Congress with the annual re-

port of the Chief of Engineer, informing the United States that the work of constructing the Sanitary District Channel had begun. Captain Marshall said (Rec. Vol. IV, 2366, 2367, 2371), Chief of Engineers Reports, 1893, Part 4, Appendix L.L. p. 2794:

"With reference to the feeling of disgust entertained by the populace towards this stream, it must be said that from the earliest settlement of Chicago the most obvious disposal of their sewage and refuse, *i. e.*, into the lake and river, has been followed. As the city grew, the old sewers were enlarged and additional ones built. The Illinois and Michigan Canal was constructed, and the contents of the river loaded with sewage was to a then sufficient degree pumped into it; later, this proved insufficient, and the canal was cut deeper to allow a flow by gravity towards the Mississippi River; this also proved in time inadequate, and it was required by the Illinois Legislature that sixty thousand cubic feet of water per minute should be pumped into the Illinois and Michigan Canal from the Chicago River to purify that stream. This requirement has never been attained. As far as ascertained, the discharge has never for any length of time for the past four years exceeded forty-five thousand
2367 cubic feet per minute, and it is not believed to have averaged much, if any, above one-half the legal requirements, or thirty thousand cubic feet per minute. To purify the North Branch, pumping works and a tunnel from Lake Michigan to the North Branch at Fullerton avenue have been for years in use. Lake water is pumped through this tunnel and creates a feeble current towards the main river. This supply forms part of the thirty thousand to forty-five thousand cubic feet per minute pumped into the Illinois and Michigan Canal at Bridgeport.

The insufficient discharge of the pumps into the canal results, in rainless weather in a very feeble current from the lake towards the pumps at Bridgeport, and in an indescribable state of putridity and offensiveness in Chicago River, due to domestic sewage and a discharge from manufacturing establishments through the sewers into the river. At ordinary rains, upon freshets in the Desplaines or Chicago rivers draining areas, great volumes of putrescent matter are disgorged into the lake through the mouth of Chicago river threatening the water supply of the city, which in the main is taken through tunnels under the bed of the lake from two inlet cribs, situate, one north of and the other south of, and a few miles distant from the mouth of the river.

To remedy the, at times, insupportable and disgusting condition of the river and its branches; to purify the river and to preserve the city water, relief is now sought under state laws by constructing a drainage canal from the south branch of Chicago river to the Desplaines river above Joliet, capable of discharging into the Illinois River Valley from three hundred thousand to six hundred thousand cubic feet of water per minute.

It is a remarkable fact that this city, while seemingly unable or unwilling to provide funds for purifying Chicago river by pumping sixty thousand cubic feet per minute is ready to embark in, and has commenced the execution of a canal for discharging ten times that amount by gravity at a comparatively enormous expense.

This channel has been located from the south branch of the Chicago River to Lockport, and is under construction, but no provision has yet been made for channels of supply from Lake Michigan. Whatever the outcome or plans of the local officials having this work in charge may be, it can be said that the Chicago River and its branches cannot in their present condition, supply materially more
2368 than from one-third to one-half of the minimum requirements of the law, without producing currents that will be prohibitory to navigation at some of the bridges and obstructions now existing.

It is certainly evident, granting the proposition that effective channels for the purpose will be constructed, that if this method of solving the drainage problem is to be carried to conclusion, there must be a complete remodeling of Chicago River throughout both its branches, and there must be also artificial channels of large capacity to furnish even approximately effective outfalls to the sewerage systems of a great city founded on low lands extending some twenty-two miles long, and for miles back from the lake, as well as other large feeders connecting the lake with such channels.

Without criticizing in any way the local measures taken for local relief, it may be said that the state laws, if effectively executed for the purposes specified, seemingly require changes in the capacity of Chicago River and its branches that may increase, may diminish, or may even entirely destroy their value for commercial purposes. In any case under existing laws, no alteration in the capacity of Chicago River can be made without the consent of the Secretary of War, or without full examination by agencies established by Congress, and the

execution of the state laws are therefore limited by superior authority.

As before said, the navigable channel of Chicago River is now maintained by the City of Chicago by dredging out the solid matter cast into it through sewers, and dumped into it, especially in winter, by its street cleaning department. The city also maintains bridge tenders, harbor master, and vessel dispatchers, patrols the stream with fire boats; pumps inefficiently the sewage from the river into the Illinois and Michigan Canal; constructs and maintains all bridges except such as are necessary for corporate public carriers.

Riparian owners have constructed the docks and wharves, of which there are none for public use, and dredge for landings alongside.

It is estimated that the total annual expenditure of the City of Chicago on the Chicago River is $350,000, of which about $120,000 is for dredging. This latter work is the only work that can be said to be in the interest of navigation.

The expenses for pumping of sewage, for bridges, for lighting and fire service, and other expenditures, are the necessary costs of encroachments upon this public highway to be paid by the profiting parties.

The dredging also is to remove solids and filth passed by the city into this navigable stream, contrary to the
2369 laws of the United States. It is necessary that either the law be enforced and the sewers sealed, or else awaiting a change of system which is not at all contemplated to require that solid matter necessarily placed in the river by the citizens of Chicago shall be removed by them before accumulating to such an extent as to obstruct navigation.

General Remarks.

Chicago River is the most important navigable stream of its length on the globe. In the number of arrivals and departures of vessels annually it leads all harbors of the United States in tonnage it is second only to New York. In these elements it is the head of the great commerce of the lakes, but in capacity, depth, and width of navigation it is but a third-class port. Improvements are in progress along the chain of Great Lakes contemplating 20 to 21 feet depth of water at low water. Several harbors have 18 feet or more depth of channel.

Chicago Harbor has 16 feet at entrance to the river, is obstructed by three tunnels with from 16 to 18 feet of water over their crowns, and can carry through but a comparatively small part of its navigable channel exceeding 15 feet. The entire inner harbor can be regarded as only a long private slip; there are no public wharves or docks, throughout its length, including branches; it is an offensive though navigable open sewer, obstructed by an average of four bridges to the mile, and lined for a greater part of its course by wooden docks in great part built up to the waters' edge by heavy buildings, elevators, etc., that will not admit a channel against them exceeding 16 to 18 feet without damage. The docks are generally of cheap construction of piles and sheet piles reaching but a few feet below the bottom of the channel existing when they were constructed but anchored back into the bank to other piles by iron tie rods about 1 and ½ to twice the channel depth in length. The docks are backed with earth. In many cases, as stated, over these cheap docks, but on foundations of additional tiles are constructed warehouses, etc., that may be more or less damaged by dredging close to the dock line to deepen the channel.

The river at numerous points, notably near Adams and Van Buren streets, has been contracted by filling within the meandered lines to less than one-half its original width. At other places in rebuilding docks, new docks have been constructed outside the first dock line. Abutments of bridges also project into the river, and piles or
2370 rip rap stone have been placed in the stream to buttress insufficient bulkheads or docks. Bends in the river now rigidly fixed by docks, of curvature with chords of sufficient length to allow the free passage of vessels of dimensions of twenty years ago, taken in connection with obstructive bridges prohibit passage by the largest modern vessels.

At the same time the increasing value of lands for other purposes near the mouth of the river is causing grain elevators, coal yards, lumber yards and manufacturing establishments, dependent upon marine transportation either to recede farther and farther from the mouth of the river, or to go elsewhere. Some establishments have moved to South Chicago, and Waukegan and Milwaukee have also profited at the expense of Chicago.

Consequent upon this recession, vessels must pass an ever-increasing number of obstacles in reaching places of transfer of cargoes. Tugs, often two of them to a vessel,

must be employed in all movements of vessels in the river above the junction of the two branches, and it is averred by prominent vessel owners that the cost of moving one of the larger vessels from the lake to the elevators above Twenty-second street and returning it to the lake is one-half the cost of transferring the cargo from Chicago to Buffalo.

This excessive cost, due entirely to the obstructions in Chicago River, is shown by differential freights on coal and other heavy commodities to other harbors on the Great Lakes, comparing mileage and rates, against Chicago.

In the present condition of Chicago River no material widening or deepening of the channel can be effected without great expense. A large proportion of the docks or bulkheads must be constructed, and in some cases precautions are necessary to prevent damage to buildings if the water is materially deepened against their foundations.

There should always be at least 2 feet of water between the bottoms of vessels and the crowns of tunnels to guard against damages to vessels by chance obstructions of small extent lodging temporarily over the rigid crowns. To secure 18 feet available water the three tunnels under the river should be lowered until there will be from 20 to 21 feet of water over their crowns. If the improvement be made on the basis of 18 feet and the use of Chicago River and its branches be conceded by the United States to the State of Illinois as a drainage channel, of the capacity indicated by the State law,
2371 the modifications therein must be radical and costly whether the expense thereof be borne by the United States or the City of Chicago.

Heretofore, under recent river and harbor acts, the United States Government has exercised a limited control over Chicago River. It has been simply a conservative control, the United States intervening only where encroachments prejudicial to the rights of the public in the navigation of Chicago River were in question. Plans for bridges across Chicago River have been acted upon by the Secretary of War, and at least one bridge, *i. e.*, that bridge originally constructed at Canal street, has been condemned as an obstruction to navigation by the War Department and has been altered or changed by the City of Chicago upon the mandate of the Secretary of War, but not in exact accordance with that mandate

either as to plan or time. The Secretary of War has not exercised his authority under the law to stop the deposit of filth in the river, nor interfered in any way with the regulations of the city with reference to the movement of vessels and bridges in or over the stream or with local police regulations relating to this stream.

In the opinion of the engineer officer in charge of this district, for the present awaiting developments of local plans under State authority, no improvement in Chicago River should be made by the General Government; nor any public funds be expended thereon so long as the City of Chicago uses it as a dumping ground for its filth and refuse of all kinds. The City should be required to remove all deposits made therein that tend to diminish its present navigable capacity, or to cease depositing its sewage therein.

This disposition of its sewage and deposit is now a necessity to this city and it is not in accord with public policy to prevent it as long as the city continues to remove the solid residue. The United States should continue its control so far as to preserve the navigation of the river from injury.

It will soon be necessary for Congress to provide for the extension to Lake Michigan of the navigation established on the Illinois River below La Salle, and to determine to what extent, if at all, it will utilize for navigation the great channel now being cut by local authorities in the rock divide, separating Lake Michigan from the Mississippi Valley. The question is at hand and must be determined at some date not far in the future, whether the national highway will utilize this cut and Chicago River as part of this communication, or the Calumet River route in connection with this local channel, or other-
2372 wise. There are no other practicable routes. If Chicago River be adopted (which is not, in the opinion of the officer in charge, in view of the rapid extension in territorial area as well as in population of this city, advantageous to either the local population for drainage purposes or for the United States for navigation), material improvements in the Chicago River channel will be required, but as before stated, even if Chicago River be utilized, the most direct channel for navigation is not the channel demanded by the necessities for drainage by the City of Chicago. If navigable channel must be arranged to best subserve local purposes, it is evident that material modifications will be required in Chicago

River that may properly demand other navigable inlets than the one already provided at the mouth of Chicago River.

It seems, therefore, that before making appropriations for the improvement of Chicago River, the question of the future uses of this stream should be settled, whether it shall continue to be as now simply a long slip or succession of private slips, docks and wharves, utilized indeed for interstate and foreign commerce, but mainly for private and corporate gain, and for the main sewer of a great urban community, or whether it shall constitute a connecting link under federal control between the navigation of the Great Lakes and that of the Mississippi River and tributaries.

This opinion is given as required by the law of July 13, 1892, but for the information of Congress the following is respectfully submitted:

To reasonably accommodate existing commerce without extensive changes in Chicago River and without reference to future developments, the following work would be in the interest of commerce and navigation:

First. That the Chicago River from its mouth to the stock yards on the south branch and to Belmont avenue on the north branch as far as may be permitted by existing docks and wharves be dredged to admit passage by vessels drawing 16 feet of water.

Second. All encroachments on the stream by docks within the original meandered lines of the streams obstructive to navigation, as it exists today, should be removed at the expense of the encroaching parties, and obstructive bridges be required altered or changed.

To admit the passage of the largest lake vessels drawing not exceeding 16 feet of water at load draft, with no changes in the dock lines beyond the obstructive abutments of bridges and projecting obstructive angles
2373 of docks, will require 1,200,000 cubic yards of dredging, approximately, and 8,000 linear feet of docking, at an expense of about $700,000, first cost, with an annual charge for dredging of from $80,000 to $120,000 to maintain the channel.

The cost of maintenance, for reasons stated above, should evidently be borne by the City of Chicago as long as sewage is emptied into the river and the United States should be released from all damages to property by reason of the improvement in Chicago River, as required on the Calumet River.

Should a discharge of 250,000 cubic feet per minute be required through the south branch and main river, wholesale modification of bridges, tunnels and docks, and a widening of the river at many points will be required, and deepening to at least 18 feet of water below Chicago city datum with a slope necessary for this discharge, will be required at an estimated cost of $6,000,000, primarily, not including consequential damages, and an annual expenditure for maintenance of from $60,000 to $75,000.

In 1895, the United States Engineer, Captain Marshall again reported to the Chief of Engineers War Department (Chief of Engineers Reports, 1895, Appendix J. J., p. 2715, Rec. Vol. IV, 2373):

"Extract from the Chief of Engineers Reports 1895, Part 4, Appendix J J, p. 2715, being report of Capt. W. L. Marshall, United States Engineer at Chicago in charge of Chicago River and Illinois River referring to the improvement of the Illinois River. Captain Marshall said:

The City of Chicago expects to turn into the channel of the Illinois at some future time 5,000 cubic feet of Lake Michigan water per second; at some more remote period there may be 10,000 cubic feet per second, but not probably within a generation. By law it is now required to pump 1,000 cubic feet per second into that channel, so that we may expect 4,000 cubic feet per second additional discharge given to the Illinois River at low water. Discharge measurements on the Illinois show conclusively that this amount of water, or even the maximum discharge, will not produce a channel without dredging or without locks and dams equal in depth to that easily attained now at very small expense by completing the dredging required. Under any probable condition an equal or nearly equal amount of dredging will be required to give an equivalent channel in the Illinois River.
2374 The proposed discharge (5,000 cubic feet) will increase the depth of water over the crest of the Kampsville dam at low water about 8 inches, and the depth over Six Mile Bar near the mouth of the Illinois but little if any more. A low-water channel 7 feet deep will exceed in depth very materially the low-water capacity of the Mississippi River, and there can be no rational demand for one of greater capacity.

In 1895, the Board of Engineers appointed by the Secretary of War to investigate the effect of the Sanitary District Channel then being constructed addressed a letter to the Sanitary District which communication was as follows (Rec. Vol. IV, p. 2380):

"Hon. Frank Wenter, President of Board of Trustees, Sanitary District of Chicago, Chicago, Ill.:

Sir—The Board of Engineers appointed by direction of the Secretary of War to consider and report upon 'the probable effect of the operation of the Chicago Drainage Canal upon the lake and harbor levels and upon the navigation of the Great Lakes and their connecting water ways' would be pleased to receive from your Honorable Board of Trustees any information or data bearing upon the subject submitted to us, and especially the following:

First—The conclusions arrived at from investigations made by your attorney or by others as to the effects upon the levels of the great lakes by the operation of your Canal, including any mathematical analyses and discussions of the question from which these conclusions have been arrived at.

Any references to printed discussions by titles, etc., will be very much appreciated if copies cannot be furnished.

2381 *Second*—Description of the Canal, including dimensions of wetted perimeter, slopes, and character of material through which excavated.

Third—Whether any part of the inner harbor of Chicago, which includes Chicago River and its branches, will be utilized as part of the proposed Canal, and if so what amount of water you propose to take through these river channels.

Fourth—If Chicago River be utilized, what changes you propose to make in the navigable channels of the river, in dimensions, slopes and structures to adapt them to your purposes; and what additional channels of supply other than the main branch of the Chicago River; which is now the only evident connection between Lake Michigan and the proposed canal, your Board proposes to make.

In making these inquiries, the Board of Engineers consider that your Honorable Body is much interested in the solution of the questions submitted to us, and therefore desirous to aid as far as practicable in arriving at correct conclusions.

Any communications you may desire to make should be addressed to me at Detroit, Michigan,

Very respectfully,
Your obedient servant,
(Signed) O. M. Poe,
Colonel, Corps of Engineers."

On August 16, 1895, The Board of Engineers of the War Department made a report on the effect of the opening of the Sanitary District channel, which report was as follows (Rec. Vol. VI., p. 3931, 3940):

3932 Chicago, Illinois, August 16, 1895.

Brig. Gen. William P. Craighill,
Chief of Engineers, U. S. A.,
Washington, D. C.

General:

The Board of Engineers appointed by virtue of S. O. No. 14, C. S. Corps of Engineers to consider and report upon 'the probable effect of the operation of the Chicago Drainage Canal upon the lake and harbor levels and upon the navigation of the Great Lakes and their connecting waterways' submits the following report:

The Board met in Chicago, August 12, 1895, and on the 13th and 14th accompanied the officers of the Drainage Canal over the line under construction. Every facility and courtesy possible has been extended by the trustees and engineers of the canal for a full investigation of the subject matter. A brief description of the canal is extracted from the printed report furnished the Board by these gentlemen.

The Main Drainage channel of the Sanitary District of Chicago is now under contract from its confluence with the South Branch of the Chicago River, at Robey street, in the City of Chicago, to its southern terminus, in Will County, Illinois. At the southern end of the channel the

controlling works will be located. Beyond these works, the construction contemplated by the District will be the work necessary for conducting the flow from the channel in conjunction with the waters of the Des Plaines River down the declivity to and through the City of Joliet, and making such changes in the Illinois and Michigan Canal as the new conditions developed will make necessary.

The first work put under contract extended southwesterly from the Willow Springs road, and these sections were numbered consecutively Nos. 1 to 14. Average length of sections, 1 mile. Easterly from Willow Springs road, the sections are lettered from A to O, omitting J. The lettered sections are, except for a short distance near Summit, entirely in glacial drift, defined in the specifications thus: 'Glacial drift shall comprise the top soil,
3933 earth, muck, sand, gravel, clay, hard pan, boulders, fragmentary rock displaced from its original bed, and any other material that overlies the bed rock.'

The sections from 1 to 14 were put under contract in July, 1892; from A to F were put under contract late in 1892, and early in 1893; and G to M, inclusive, were contracted for in December, 1893. Sections N and O were put under contract May 2nd, and section 15, August 27th, 1894.

Earth was first broken on 'Shovel Day,' September 3rd, 1892, on the Rock Cut below Lemont.

The Des Plaines valley is traversed by the river from which it takes its name—a stream of wide fluctuations with no constant and reliable fountain supply. During some seasons its whole discharge would pass through a six-inch pipe, and at others its volume reaches 800,000 cubic feet per minute. Then it rolls majestically along, flooding the whole valley. Such being the situation, control of this stream was a condition precedent to the successful prosecution of the work upon the main Channel. This control has been secured by the outlay of nearly $1,000,000 in constructing what is known as the River Diversion Channel.

About 13 miles of new river channel had to be excavated with the location of the Main Drainage Channel, and about nineteen miles of levee built to divorce the waters of the Des Plaines watershed from the channel which is to receive the waters of Lake Michigan and pass them on to the Mississippi River, via the lower Des Plaines and the Illinois Rivers. The width of the River Diver-

sion Channel on the bottom is 200 feet, side slopes 1½ to 1, grade generally 12-100 per 1,000 feet.

At the head of this River Diversion it was necessary to provide a safety valve in the form of a spillway, to allow surplus water to flow towards Chicago, because arrangements have not as yet been perfected for carrying the entire flood waters of the Des Plaines through Joliet.

This spillway is a concrete dam capped with cut stone, and its wings faced with stone masonry; it is 397 feet long and its crest is 16.25 feet above Chicago datum (this datum is referred to the low water of Lake Michigan of 1847, and is 579.61 above sea level at Sandy Hook). No water flows over this spillway until the volume passing the water gage above it reaches 300,000 cubic feet per minute.

The cross-section of the earth sections from A to E inclusive is 202 feet on the bottom, side slopes two to one.
3934 This section extends for about 500 feet into the west end of F and then reduces to 110 feet on the bottom, preserving the same side slopes. The explanation for this change of cross-section is as follows: Throughout the rock sections, and those sections in which there is a preponderance of hard material, or where rock may appear, the section adopted is designed according to law for a flow of 600,000 cubic feet of water per minute, which means provision for a population of 3,000,000 people. The narrow channel provides for a flow of 300,000 cubic feet per minute, or for about the present population of Chicago. The enlargement of the narrow channel can be made by the easier method of excavation, such as dredging; whenever the needs of the city require it. The grade throughout the lettered sections is one foot in 40,000 (.025 per 1,000 feet) and the bottom of the channel at Robey Street is 24.448 feet below datum. The numbered sections from No. 1 to No. 6 inclusive are underlaid with solid rock. The width of the bottom in rock, is 160 feet, and walls of masonry laid in cement will be built upon the rock surface to a height of five feet above datum. Section 7 to 14, inclusive, are in solid rock; width at bottom 160 feet, sides vertical, prism taken out in three stopes with offset of six inches on each side for each cut, making top width of 162 feet; grade in rock 1 foot in 20,000 (.05 per 1,000).

Section No. 15 is also in rock and its cross sections is enlarged at its south end so as to form a 'windage basin' in which large vessels may be turned around. The controlling works are located on this section. These works

will consist of gates or movable dams by which the flow of water from the Main Channel into the tail race, which is to deliver the outflow into the Des Plaines River, can be controlled.

This river below Lockport follows the trough of the valley down a steep declivity to the canal basin in Joliet. The fluctuations in Lake Michigan, by varying slope of water surface, will be felt at the controlling works, and provisions must be made to meet these fluctuations within a range of five feet above datum and eight feet below, or an extreme oscillation of 13 feet. The fall from datum at the controlling works to the level of the upper basin will be about 42 feet, in a distance of about 4⅓ miles. As the plans for controlling works have not been finally adopted by the Board of Trustees they cannot now be discussed.

The total amount of excavation involved in the construction of the Main Channel is 26,077,765 cubic yards of
3935 glacial drifts and 12,071,668 cubic yards of solid road, or an aggregate of 38,149,433 cubic yards, to which must be added the material excavated from the River Diversion; glacial drift, 1,564,403 cubic yards; solid rock, 258,926 cubic yards; total River Diversion, 1,823,329; grand total Main Channel and River Diversion, 39,972,762 cubic yards. All of this work is now under contract and in addition thereto 384,958 cubic yards of retaining wall.

In response to the request of the Senior Member of the Board the Board of Trustees of the Sanitary District of Chicago has furnished a report on Lake Level effects on account of the main channel of the Sanitary District of Chicago containing briefs by Trustee L. E. Cooley, C. E., and by Thos. T. Johnston, Assistant Chief Engineer, accompanied by numerous blue prints.

These papers present a full discussion of the subject as viewed by the canal officials, and will be found in the Appendix marked A.

What Is the Outflow of the Lower Lakes?

In November, 1891, the Chief of Engineers U. S. A., at the request of the Secretary of the American Society of Civil Engineers (who had been asked by the Chief Engineer of the Montreal Harbor Commission of Canada, to suggest the subject), ordered a set of observations made to determine the amount of water flowing down the Niagara River. The time was especially propitious as the water was then very low.

The results of these measurements were somewhat unexpected, and they were repeated in May, 1892. The second set corroborated the first, and the whole formed the subject of a report to the Chief of Engineers, which appeared in his annual report of 1893, page 4364, and following. But, as the subject was important, the 'Engineeering News' anticipated the appearance of the official report by publishing in its issue of March 8, 1893, this report, with the permission of the Chief of Engineers. This publication was the first ever made in which as a result of careful measurements a relation between the level of the lakes, and their outflow, or discharge, had been established and given to the public. Prior determination of this discharge had not attempted to detect this relation, and nothing more than a general determination of a season's work had been published.

In all plans for the Chicago Drainage Canal the early measurements had been taken, and those studying the subject chose such isolated figures as suited them best.

3936 The report of 1892, being so late in appearance, long after the Drainage Canal was put under construction, escaped the notice of many who are interested in navigation, for two reasons. Some were too busy to see anything, unless specially brought to their notice. Others thought the whole matter already fully canvassed, and settled. It is true there is nothing showing that the consent of Congress had been asked, for this enterprise. Certain that the subject had not been treated as an Interstate affair; to say nothing of its being an International affair. The United States has always been slow to move; with its many sleeping rights it has for many years been loath to exercise them. Not till 1888 did it begin to exercise positive legislation over its navigable waters in order to preserve them for all its citizens. Each River and Harbor bill since then is found to have sections strengthening the hands of those who wish to keep the waterways open, and in good order for all classes of navigators. Not till 1890 had any prohibitive clauses been enacted into laws forbidding, for example, the destruction of channels by improper dumpings. Saw mills went their own unchecked way every year clogging up the streams. Railroads bridged all smaller streams, in the states, without interference from the United States. Many other features can be quoted. But it is sufficient to say that all that is now changed. The adopted policy is to defend, as well as improve all water courses, now navigable, or probably navigable in the reasonably close future. Wa-

terways are under the charge of the United States, and there is no likelihood of their being abandoned for some time to come.

With this an established fact it is impossible to think that U. S. supervision shall not be extended to the Chicago Drainage Canal in due time. Under whatever law built, and for whatever purpose constructed, just so soon as it is shown that that canal affects, or becomes a part of the system of navigable waterways of the United States some supervision or control of it must follow. When boats use it for harbor purposes; when its waters add to the Illinois River, or take from the lakes, they alter natural conditions and the matter rises for consideration under national authority.

The water levels of the Great Lakes are very delicate. Storms, barometric changes, rainfall, even tidal changes are felt. Records show at Buffalo no less than 13 feet as a total possible change, between the lowest and the highest gage readings. Each lake is a basin. The water is constantly pouring in from not only one, but several
3937 inlets. The overflow, however, is now always out of the one outlet provided for that purpose; the second one formerly at Chicago, has been plugged up.

As in our basins when the water rises enough to take two, three, or more of the small holes to carry it off, it is always to be noted that those holes are always carrying that surplus off. They do not wait until the water has time to pass from one end to the other. In the same channel the head alone governs the rate of outflow, and that head is measured by the gage reading at the outlet. The supply of water in the lake: The net supply, allowing for evaporation, is the sole cause of the outflow. That supply depends solely upon rainfall, but the lake when it receives more than it has been receiving must discharge more. When it has less there is less to run out. If the outlet be dug down, or new ones made the water runs off faster than it ran off before.

The outflow is instantly affected by a changed inflow; Provided there is enough such to increase or reduce the head. If we have a rainfall of one inch over the lake area (and such are not uncommon events), there is a head of one inch to run off. But if there are two outlets to run out of, instead of one this inch must run off sooner than through the one.

If the new outlet should reduce the levels of Lake Michigan and Huron about 6 inches this effect will be

produced in full in about two years; it is not then a question of many years as some suppose.

We may feel very sure, therefore, that in this question two points are certain.

1st. The drainage canal is not solely a State affair; but a national one.

2nd. The tapping the lakes must affect their levels. But it is said, first, that the changes in levels does not concern shippers, and then that at most the affects will be trifling.

If one watched carefully the course pursued by shippers one would see that as a rule each vessel carries all that it can take, and get out of its port, or into that it intends to reach. Vessel owners, and managers are very shrewd, watchful men. They know what they can safely carry allowing for storms, and short detentions arising from passing causes. They average pretty well the practicable depths, and carry all the channels will stand. They are as conversant as are theorists about the effects of storms, but they keep good watch on ruling depths. Now should it be certain that these average depths were reduced three
3938 inches, or six inches, they must load accordingly. And not only the large boats, but also the small ones using the small harbors that the large ones cannot go into. All must lose the three, or six inches, as it may be; and not for one, or more trips, but for all trips, and for all time; a diminution of capacity is not a single tax, but a continuous one. A vessel that when light draws six feet, and loaded twelve feet, must lose three inches out of 72, say four per cent in capacity each loading; a vessel drawing 12 feet light and 20 feet loaded, would lose somewhat over three per cent in capacity at each end every loading.

Should the loss of levels be six inches instead of three, then these figures become doubled. Will the loss be six inches or will it be three? This is an important question and we have only the Niagara River discharge observations from which to answer it. These cover a range of about 1 foot and eight-tenths. There were scattering observations outside these limits, but the mass of results was secured between gage readings, mean lake level, the highest, and—1. '85. The 'smooth curve' as published enables us to note the fall of 0′ .53 on the gage per 10,000 cubic feet per second for the first foot of fall and 0′ .44 for the whole.

These observations, especially at the lower readings are erratic and indicate a need for more measurements, especially at these levels. This lower portion of the gage should be studied and additional observations made, and the Board is a unit in suggesting the importance of a series of gaging of the St. Clair River at the present time for this purpose, and to furnish additional knowledge of the relation between gage readings, and discharge. The subject is of such general bearing upon the navigation of the lakes, that it demands careful treatment, and full data. The Niagara data do not show how much Lakes Huron and Michigan would be lowered, even if 0'53 were the net loss to Lake Erie. The opinion expressed by Mr. Johnson that the effect on the two upper lakes would be some 15 per cent greater than upon Erie would seem to point to a probable loss of say 0'61. This possible loss of seven inches certainly is important enough to justify careful measurements of the discharge through the St. Clair. It is true that the law as it stands, and the intention of the Trustees contemplates the abstraction of only 300,000 cubic feet under present conditions, but after the canal is opened measurements would not be so instructive, and we must assume that ultimately the entire 600,000 cubic feet per minute will be drawn from Lake Michigan as required by the State Law.

3939 The abstraction of 10,000 cubic feet of water per second from Lake Michigan will lower the levels of all the Lakes of the system except Lake Superior and reduce the navigable capacities of all harbors and shallows throughout the system to an extent that may be determined, if at all, by actual measurements only. Under the laws of the United States these changes in capacity cannot be made without Federal authority, and to enable the executive officers of the United States to act advisedly in the matter it is necessary in the opinion of the Board not only that these measurements be taken but that the money cost of restoring the navigable depths in channels and harbors be carefully estimated.

In this connection the Board submits without expression of opinion an estimate prepared by Mr. Charles H. Keep, Secretary of the Lake Carriers Association, of the commercial losses in carrying capacity of the Lake fleet of one, three or six inches.

(Appendix Marked B.)

The Board notices that the same peculiarity exhibited by the Niagara discharge curve, is pointed out by Mr.

Johnston as existing in the Morris, Ill., and South Branch Chicago River curves. (See page 25 Appendix A 1.)

The Board also notes Mr. Johnston's conclusions on page 23, Appendix A-1, that 'applying the reasoning to the St. Clair and Detroit Rivers, then the value of Q'—Q may be taken from the diagrams illustrating the tables before described, the only uncertainty being as to the value of 'd.' Suppose 'd' to be unity, and the mean depth 20 feet. Then Q'—Q will equal something greater than 20,000 cubic feet per second," which practically corresponds with the deductions made from Niagara River observations.

So many uncertainties arise in the application of hydraulic formulae that the only way to ascertain the approximate discharge of these streams is to measure them for periods long enough to eliminate accidental fluctuations and to cover all stages.

While the navigable capacity of all harbors and channels on the Great Lakes below St. Marys Falls will be injuriously affected by a diminution in depth, the navigability of the inner harbor of Chicago will be diminished also by the introduction of a current therein, which in the present condition of the river even with the minimum
3940 flow of 5,000 cubic feet per second or 300,000 cubic feet per minute is entirely inadmissible. The estimates of the effect of the Drainage Canal upon this harbor should also consider this element.

The Board of Trustees have not yet determined upon a plan of treatment of this navigable channel, and their plans may be such as may improve, impair or destroy its utility as a navigable river.

All of which is respectfully submitted.

O. M. Poe,
Col. Corps of Engineers,
Br. Brig. Genl. U. S. Army.

E. H. Ruffner,
Major of Engineers, U. S. Army.

W. L. Marshall,
Major Corps of Engineers."

On June 16, 1896, the Sanitary District of Chicago applied to the Secretary of War for a permit to improve the Chicago River in order to secure the necessary water through the Chicago River to make available the artificial channel

then under construction, a map accompanied the request showing just what work the Sanitary District proposed to do in the Chicago River, said letter is attached to the answer, as Exhibit H. (Rec. Vol. VIII, pp. 120, 121; This Narrative p. 88.) Under date of July 3, 1896, Joseph P. Doe, Acting Secretary of War, approved the plan submitted. (Rec. Vol. VIII, p. 121.)

"July 3, 1896.

Sir: I have the honor to acknowledge the receipt of your letter of 16th ultimo, requesting permission to make certain changes in the capacity of the channel of the Chicago River for drainage purposes at points indicated on the map accompanying the application, and in reply beg to say that upon investigation it is found that the permission requested can be granted upon the following conditions:

1. That while the general plan is approved, the Sanitary District of Chicago must furnish plans in triplicate on an enlarged scale showing each proposed new bridge, each by-pass and each new dock or wharf proposed to be built, in order that the Secretary of War may act intelligently in each case.

2. That this authority shall not be interpreted as approval of the plans of the Sanitary District of Chicago to introduce a current into Chicago River. This latter proposition must hereafter be submitted for consideration."

November 16, 1897, pursuant to request of the Sanitary District, the Secretary of War issued a permit to widen the Chicago River between Quincy and Harrison streets in certain respects. The request and permit are as follows (Rec. Vol. VI, pp. 3575, 3576):

"B. A. Eckhart, Esq.,
President The Sanitary District of Chicago,
Rialto Building,
Chicago, Ill.

The Sanitary District of Chicago.

Chicago, October 28, 1897.

To the Hon. Russell A. Alger,
Secretary of War,
Washington, D. C.

Sir:

I have the honor of transmitting to you through Maj. W. L. Marshall, Corps U. S. Engineers, plats showing the proposed widening of the Chicago River between Quincy and Harrison streets, to conform to the plans of this District for securing an adequate flow of water through the said stream. Our general plans have been heretofore submitted to the War Department and in the communication under date of July 3, 1896, signed by the then acting Secretary of War, Joseph B. Doe, have received a qualified approval subject to the general requirement that plans for each separate division of the work shall be submitted for specific approval. We respectfully ask your approval of the plans now transmitted.

Very respectfully,

Thomas Kelly,
President.

1st Indorsement,

U. S. Engineer Office,

Chicago, Ills., October 29, 1897.

Respectfully forwarded to the Chief of Engineers U. S. A.

The works indicated are by-passes and docks indicated on the general plans conditionally approved by the Acting Secretary of War, July 3, 1896. (E. D. File No. 15715/5).

As these works make possible a material improvement in the capacity of Chicago River for navigation in the vicinity of Adams and Van Buren streets, I respectfully recommend that the necessary authority to do the work be granted by the Secretary of War, subject to all the conditions attached to the original authority dated July 3, 1896.

W. L. Marshall,
Maj. Corps Engrs.

3576 Form No. 5.

Whereas, by Section 3 of the Act of Congress, approved July 13, 1892, entitled 'An Act making appropriations for the construction, repair, and preservation of certain public works on rivers and harbors and for other purposes,' it is provided that, without the permission of the Secretary of War, it shall not be lawful to build any wharf, pier, dolphin, boom, dam, weir, breakwater, bulkhead, jetty or structure of any kind outside established harbor lines or where no harbor lines are or may be established in any port, homestead, haven, harbor, navigable river, or other waters of the United States, in such manner as shall obstruct or impair navigation, commerce, or anchorage of said waters; or to excavate or fill, or in any manner to alter or modify the course, location, condition, or capacity of any port, roadstead, haven, harbor of refuge, or inclosure within the limits of any breakwater of the channel of any navigable water of the United States, unless approved and authorized by the Secretary of War;

And whereas, the Sanitary District of Chicago has submitted to the Secretary of War for his approval the attached plans for the widening of the Chicago River between Quincy and Harrison streets of said city, by the construction of by-passes and docks;

Now, Therefore, This is to certify that the Secretary of War hereby approves and authorizes the work shown on said plans upon the following conditions:

1. That while the general plan is approved, the Sanitary District of Chicago must furnish plans in triplicate on an enlarged scale showing each proposed new bridge, each by-pass, and each new dock or wharf, proposed to be built, in order that the Secretary of War may act intelligently in each case.

2. That this authority shall not be interpreted as approval of the plans of the Sanitary District of Chicago to introduce a current into Chicago River. This latter proposition must be hereafter submitted for consideration.

3. That it will not cover obstructions to navigation, by reason of this work while in progress, or when completed.

4. That the United States shall not be put to expense by reason of this work.

5. That this authority shall expire by limitation in two years from date unless extended.

Witness my hand this 16th day of November, 1897.
R. A. Alger, Secretary of War.
(War office Seal.)"

November 30, 1898, the Secretary of War granted a permit pursuant to the request of the Sanitary District to construct a coffer dam around the east side of the center pier of the Adams Street Bridge, in connection with the improvement of the Chicago River. (Rec. Vol. VI, p. 3578.)

January 13, 1899, pursuant to the request of the Sanitary District, the Secretary of War granted a permit to remove Taylor Street Bridge across the Chicago River. (Rec. Vol. VI, p. 3580.)

March 10, 1899, permit was granted by the Secretary of War for the erection of a bridge at Taylor street in connection with the river improvement. (Rec. Vol. VI, p. 3585.)

May 12, 1899, pursuant to the river improvement plan, permit was granted by the Secretary of War to construct a coffer dam along the west side of the Chicago River at certain place. (Rec. Vol. VI, p. 3582.)

On February 9, 1898, the Sanitary District of Chicago invited the Committee on Rivers and Harbors of the House of Representatives to make an inspection of the Chicago

River and the main channel of the Sanitary District then nearing completion. (Rec. Vol. IV, p. 2381.)

On February 23, 1898, the Committee made the investigation. (Vol. IV, p. 2382.)

On April 24, 1899, Major Marshall, of the Corps of Engineers of the United States Army, acting as United States Engineer at Chicago, wrote to the Chief of Engineers recommending that a permit to open the main channel of Sanitary District be issued by the Secretary of War and Chief of Engineers. His report is as follows (Rec. Vol. VI, pp. 3586-3588):

"United States Engineers Office,
#1637 Indiana Ave., Chicago, Ill.

April 24, 1899.

Brig. Gen. John M. Wilson,
Chief of Engineers, U. S. A.,
Washington, D. C

General:

I have the honor to report as follows on the application of the trustees of the Sanitary District of Chicago for authority to open their drainage canal. It is a strange fact that this city has expended, or will expend, over $30,000,000 with the intention of diverting an apparently unlimited amount of water from the Great Lakes to the Mississippi drainage area for sanitary purposes without finding out whether such diversion would be allowed by the great interests of the United States and the Colonies of Great Britain along the chain of Great Lakes in the navigation of the rivers and harbors of the Great Lakes. Now, they ask the authority of an executive officer of the United States to open a channel that will to some unknown extent, lower the levels of all the Great Lakes below Lake Superior and of their outlets, introduce a current also unknown and not to be ascertained otherwise than by actual experiment, in Chicago River, the most important navigable river of its length on the Globe, but which is already obstructed by bridges, masses of masonry and bends, and of difficult navigation at best.

The possible effects of this diversion are not known further than that to some unknown degree they will be injurious. Whether the amount of this injury will be so small as to be accepted by the interests affected, in view of the manifest advantages to and apparent necessities of their neighbors, cannot be determined by other than the interests themselves.

It is clear to me that I am not competent to make a recommendation as to what should ultimately and definitely be done.

3587 The matter of what effect the opening of this channel would have on the levels of the Great Lakes has been heretofore submitted to a Board of Engineers. The Board reported that the Great Lakes would be lowered, but that there was not sufficient data to determine the exact effects of the proposed discharge, and recommend extended investigations, which it is believed are being carried on now by the Deep Waterways Commission or Board. They have not reported. In my opinion the abstraction of from 300,000 to 600,000 cubic feet per minute will permanently lower Michigan, Huron and Erie from three to eight inches; not more than eight nor less than three, corresponding to an extreme reduction of from 160 to 466 tons in carrying capacity of the large vessels of the lakes, and that it will take from three to four years for this full effect to be obtained. But the state law is unlimited in its requirements. 20,000 cubic feet per minute must be taken from Lake Michigan for each 100,000 population of the District; already nearly 400,000 cubic feet must be taken, and at the same ratio of increase for a few decades, in a very short time there must be taken 1,000,000 c. ft. per minute under this indefinite law. The amount should be limited and the injurious effect stopped somewhere.

The mean current to be introduced in Chicago River upon the opening of the canal is estimated by the Engineers of the Drainage Board at 1¼ miles per hour, or 110 feet per minute. This is simply an assumption that with such velocity in an unobstructed river, the amount of 300,000 cubic feet per minute can be discharged through Chicago River,—but I have seen this river so jammed with vessels, drawing all the water that is in it, —that by leaping from deck to deck I could cross the river. What the velocity would be in such conditions, with Lake Michigan on one side and a great fall on the other side of such vessels, no one knows. But it is a

simple mathematical problem to determine the effect on steel-plate vessels of from 2,000 to 4,000 tons mass drifting upon or striking stone piers with a velocity of near 2 feet a second. They will go to the bottom.

Individually I have to say that I am in entire sym-
3588 pathy with the people in their effort to purify their water supply. I have lost my only son from typhoid fever, produced, I believe from drinking water polluted by defective drainage at Chicago, which this channel will correct. In every proper way I have aided the officers of the Drainage District. I would like further to aid them, but I believe this question to be entirely out of my sphere, and too great and important for me even to venture an opinion or make a recommendation about. Yet I may venture to suggest that the entire subject be referred to Congress for final solution, and that a conditional permit or authority be granted to the authorities of the Chicago Sanitary District by the War Department, awaiting action by Congress, to open their channel, and under the following conditions:

1st. That if, at any time, it becomes apparent that the current created by such drainage works in the South and Main branches of Chicago River, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago River and its South Branch.

2nd. That the Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago River. With 300,000 cubic feet per minute discharge, it will take one year to lower the level of Lakes Michigan and Huron 1/10 of a foot, and several years to reach the maximum permanent effect of this discharge, which will not probably much exceed three inches, so that the main injury to navigation, if any that can be expected before action by Congress, will be in Chicago River, and that can be at once abated.

All the changes made by the Sanitary District of Chicago, taken by themselves, have been such as to increase the navigable capacity of Chicago River. Taken in connection with the current to be introduced I am not able to say that the river will be as navigable as it was before these changes were made. The changes materially lessen

the probable injury to navigation of this current, at the points where the changes have been or will be made.

I believe their channel will be entirely under control and that if the discharge be injurious it can be at once and at any time shut off, and it is evident that the War Department should preserve the right to control the current and discharge through the Controlling Works of this channel.

Very respectfully,
Your obedient servant,
W. L. Marshall,
Maj. Corps of Engineers, U. S. A."

On May 8, 1899, pursuant to the recommendations of Major Marshall and the Chief of Engineers, the Secretary of War issued a permit for the opening of the Sanitary District Channel. (Rec. Vol. VIII, pp. 44, 45; Narrative p. 21.)

Whereas, by Section 10 of an act of Congress approved March 3, 1899, entitled 'An Act making appropriations for the construction, repair and preservation of certain public works, on rivers and harbors, and for other purposes,' it is provided that it shall not be lawful to alter or modify the course, location, condition or capacity of the channel of any navigable water of the United States unless the work has been recommended by the Chief of Engineers and authorized by the Secretary of War prior to beginning the same:

And whereas, the Sanitary District of Chicago, a municipal corporation, organized under the laws of the State of Illinois, has constructed an artificial channel from Robey street, Chicago, to Lockport, and has been heretofore granted permission by the Secretary of War to make certain improvements in the Chicago river for the purpose of correcting and regulating the cross section of the river so as to secure a flowage capacity of 300,000 cubic feet per minute with a velocity of one and one-quarter miles an hour, it being intended to connect the said artificial channel with the west fork of the south branch of Chicago river at Robey street in the said City of Chicago.

And whereas, The said Sanitary District of Chicago has now applied to the Secretary of War for permission to divert the waters of the said Chicago river and cause

them to flow into the said artificial channel at Robey street as aforesaid;

And whereas, The said Sanitary District of Chicago represents that such movable dams and sluice gates as are necessary to, at all times, secure absolute and complete control of the volume and velocity of flow through the Chicago river have been constructed;

Now therefore, The Chief of Engineers having consented thereto, this is to certify that the Secretary of War hereby gives permission to the said Sanitary District of Chicago to open the channel constructed and cause the waters of Chicago river to flow into the same, subject to the following conditions:

1. That it be distinctly understood that it is the intention of the Secretary of War to submit the questions connected with the work of the Sanitary District of Chicago to Congress for consideration and final action, and that this permit shall be subject to such action as may be taken by Congress.

2. That if, at any time, it become apparent that the current created by such drainage works in the south and main branches of the Chicago river, be unreasonably obstructive to navigation or injurious to property, the Secretary of War reserves the right to close said discharge through said channel or to modify it to such extent as may be demanded by navigation and property interests along said Chicago river and its South Branch.

3. That the Sanitary District of Chicago must assume all responsibility for damages to property and navigation interests by reason of the introduction of a current in Chicago river.

Witness my hand this 8th day of May, 1899.

R. A. Alger, *Secretary of War.* (Seal War office.)
John M. Wilson, *Brig. Genl. Chf. of Engrs. U. S. A.*"

On January 17, 1900, the Sanitary District Channel was opened, and water has flowed out of Lake Michigan through the Chicago River down the Sanitary District Channel continuously since that day. (Cooley Rec. Vol. III, p. 174; Narrative p. 293.)

On June 20, 1900, Major Willard, United States Engineer at Chicago, made a full report upon the operation of the Sanitary District Channel and its effect upon navigation in the Chicago River. In this report Major Willard said: (Rec. Vol. IV, pp. 2385, 2386):

"There is no doubt that the reversed current in Chicago River has increased the difficulty of navigating it with the large boats now demanded by commerce, but it is a noteworthy and gratifying fact, not unexpected by me at least, that the pilots have been quick to adapt themselves to the new conditions and I have little doubt but that they could handle their boats safely even in greater currents than now obtain.

If I have not overestimated pilots' skill, and considering the immense benefit of the Drainage Canal to the City of Chicago since its opening only a few months
2386 ago, I recommend that no restrictions be placed upon the legal requirements of flow into the Sanitary Canal, unless it should be found absolutely necessary to do so.

The Engineer Department, the City of Chicago, and the Sanitary District are of one mind as to the need of improving Chicago River, and are co-operating heartily to that end, and large sums are appropriated and being expended judiciously by each for the objects in view. The interests of navigation are not only being protected, but are being advanced practically sooner than could be hoped for in the usual course."

On April 26, 1900, the Sanitary District submitted plans for the improvement of the south branch of the Chicago River from Lake street to Ashland avenue and asked the Secretary of War to issue a permit for such improvement. (Rec. Vol. VIII, p. 122; Narrative p. 90.)

On June 7, 1900, the Sanitary District again submitted plans for the widening of the south branch of the Chicago river between 12th street and Ashland avenue to a uniform width of 200 feet. (Rec. Vol. VIII, p. 123; Narrative p. 91.)

On July 11, 1900, the Secretary of War approved the plans and issued the permit as requested on April 26, 1900. (Rec. Vol. VIII, p. 124; Narrative p. 92.)

On July 11, 1900, the Secretary of War also approved the plans and issued the permit as requested in the application of June 7, 1900. (Rec. Vol. VIII, p. 125; Narrative p. 93.)

On April 9, 1901, the Secretary of War issued an order directing the Sanitary District to reduce the flow through the Chicago River to 200,000 cubic feet per minute instead of the withdrawal of over 300,000 cubic feet because of the velocity of nearly three miles per hour in the Chicago River, which was dangerous to navigation in its then condition. (Rec. Vol. VIII, p. 45; Narrative p. 23.)

On July 23, 1901, the Secretary of War amended the order of April 9th, permit the Sanitary District to flow 300,000 cubic feet per minute between the hours of 4 P. M. and Midnight. (Rec. Vol. VIII, p. 46; Narrative p. 24.)

On December 5, 1901, upon application of the Sanitary District the Secretary of War issued a permit authorizing a flow of 250,000 cubic feet per minute throughout the twenty-four hours of the day. (Rec. Vol. VIII, p. 47; Narrative p. 24.)

On January 17, 1903, the Secretary of War issued a permit authorizing the Sanitary District to increase its flow to 350,000 cubic feet per minute until the 31st day of March, 1903 after which date it was to reduce it to 250,000 cubic feet per minute. (Rec. Vol. VIII, p. 48; Narrative p. 25.)

On September 11, 1907, the Secretary of War issued an order approving the plans for the proposed drainage channel to connect Lake Michigan at Wilmette, Illinois, with the north branch of the Chicago River with the provision that the total diversion of water from Lake Michigan should be no greater than already authorized by the War Department. (Rec. Vol. VIII, p. 115; Narrative p. 81.)

On June 30, 1910, the Secretary of War authorized the Sanitary District of Chicago to open the channel from the Calu-

met River to its main channel with the provision that the total amount of water withdrawn from Lake Michigan should not exceed the War Department permit. (Rec. Vol. VIII, p. 116; Narrative p. 82.)

On January 27, 1897, Major Marshall made a preliminary examination of the Upper Illinois River and the Lower Des Plaines River with a view of the extension of navigation from the Illinois River to Lake Michigan at Chicago in compliance with the requirements of the Rivers and Harbors Act of June 3, 1896, which report was transmitted to the Congress of the United States as House Document 353, 54th Congress, 2nd Session. (Rec. Vol. IV., p. 2202.) This letter of Major Marshall is the basis of survey provided by the Rivers and Harbors Act of March 3, 1899.

"54th Congress, 2d Session. House of Representatives.
Document No. 333.

PRELIMINARY EXAMINATION OF THE UPPER ILLINOIS RIVER AND LOWER DES PLAINES RIVER, ILLINOIS.

Letter from the Secretary of War, Transmitting, with a Letter from the Chief of Engineers, a Report of a Preliminary Examination of the Upper Illinois River and Lower Des Plaines River, Illinois.

March 2, 1897.—Referred to the Committee on Rivers and Harbors, ordered to be printed.

War Department,

Washington, D. C., March 3, 1897.

Sir: I have the honor to enclose herewith a letter from the Chief of Engineers dated March 2, 1897, together with a copy of a report from Maj. W. L. Marshall, Corps of Engineers, dated January 27, 1897, of a preliminary examination made by him in compliance with the provisions of the river and harbor act of June 3, 1896, of the upper Illinois River and lower Des Plaines River, Illinois.

Very respectfully,
DANIEL S. LAMONT,
Secretary of War."

2203 "Washington, D. C., March 2, 1897.

Sir: I have the honor to submit the accompanying report of January 27, 1897, by Maj. W. L. Marshall, Corps of Engineers, of the results of a preliminary examination of the upper Illinois River and lower Des Plaines River, Illinois, with a view to extension of navigation from Illinois River to Lake Michigan at or near Chicago, made in compliance with requirements of the river and harbor act of June 3, 1896.

Major Marshall states that the locality embraces an important commercial route between the Great Lakes and the Mississippi River system, and its utility and worthiness have long been recognized by Congress.

The division engineer, Col. Henry M. Robert, Corps of Engineers, is of the opinion that the upper Illinois and the lower Des Plaines rivers are worthy of improvement, and I concur in his views.

It is estimated that the cost of the necessary survey and preparation of detailed plans of improvement will be $75,000.

Very respectfully, your obedient servant,

JOHN M. WILSON,
Brig. Gen., Chief of Engineers, U. S. Army.

Hon. DANIEL S. LAMONT,
Secretary of War."

"PRELIMINARY EXAMINATION OF UPPER ILLINOIS RIVER AND LOWER DES PLAINES RIVER, ILLINOIS, WITH A VIEW TO EXTENSION OF NAVIGATION FROM ILLINOIS RIVER TO LAKE MICHIGAN AT OR NEAR CHICAGO.

United States Engineer Office,

Chicago, Ill., January 27, 1897.

General: In accordance with your letter dated August 11, 1896, I have the honor to submit the following report upon a preliminary examination of 'the upper Illinois River and lower Des Plaines River, with a view to extension of navigation from Illinois River to Lake Michigan at or near Chicago,' directed by the river and harbor act of June 3, 1896.

* * *

The sanitary district of Chicago has nearly completed
2204 a canal for drainage purposes from Chicago River at Robey street to near Lockport from 18 to 22 feet in depth below the proposed water surface, and varying in width from 160 feet in rock to more than 200 feet in earth, a length of 28 miles, which may be made available as part of any enlarged waterway over the route in question, and is of much greater dimensions than required by any commercial canal adapted for the conditions and requirements of present or prospective traffic by water between Lake Michigan and the region along the water courses of the Mississippi Valley. To comply with the law of the State of Illinois under which this drainage canal is constructed — it has been constructed of a capacity to discharge 600,000 cubic feet per minute through the section excavated in rock and 300,000 cubic feet per minute throughout the earth section— the law requires a discharge of 20,000 cubic feet per minute for each 100,000 inhabitants of the drainage district, which at present requires more than 300,000 cubic feet and in a few years will require the full 600,000 cubic feet discharge through the canal. The taking of water from Lake Michigan, however, for drainage purposes (or rather for dilution of sewage) has not yet been authorized by Congress. This deep channel abruptly terminates at Lockport, and it is proposed to discharge the water through controlling gates into a non-navigable tail race down the slope to and through the City of Joliet into the lower Des Plaines and Illinois rivers. Any navigable channel, therefore, constructed in continuation of the drainage canal must connect with this canal at Lockport and terminate at or above LaSalle, about 66 miles distant, but the lockage after the opening of the drainage canal will be reduced by at least the amount that the increased discharge will raise the water surface of the Illinois River at LaSalle, increased by the slope in the drainage canal from Lake Michigan to Lockport, or, say, at least 12 feet when the drainage canal is actually discharging. This will result in reducing the number of locks required in any
2205 of the proposed schemes by one, but will substitute an obstruction due to the current in the canal and river, repeated in each pool of the river, if the natural channel be improved.

* * *

The trustees of the Chicago sanitary district are constructing their canal with fixed bridges with 22 feet clear

headroom over the canal. This is ample headroom for a commercial barge canal of the largest capacity, and the difference in cost between fixed and drawbridges crossing the canal between Chicago and Lake Joliet, with a reasonable allowance for difference in cost of operation, is probably sufficient to construct the canal from the present terminus of the drainage canal to Lake Joliet of from 8 to 10 feet depth, with locks suitable for the passage of the largest Mississippi River barges. Mississippi River towboats could then carry their tows to Lake Joliet, then transfer them to more handy tugs for passage through the more obstructive canal portion of the route. For an 8-foot channel from Lockport to Lake Joliet the estimated cost in 1890, exclusive of bridges, was $3,900,000. Swing bridges from Chicago to Lake Joliet were estimated at $3,653,000. The cost of operating the swing bridges would far exceed the cost of operating the locks without any corresponding advantages for a commercial canal, other than sentimental, over the part of the route where towing on the Mississippi River style cannot be applied.

Conclusion.

1. In my opinion the surveys already made are in sufficient detail for preliminary estimates of the cost of any suitable extension of the navigation of the Illinois River to Lake Michigan that does not involve enlargement of the Illinois and Michigan Canal from Joliet to LaSalle.

2. That prior to embarking in any such improvement it is advisable to secure from the State of Illinois the State works along the Illinois River and such parts of the Illinois and Michigan Canal as may be utilized; also to thoroughly complete the lower Illinois River improvement which has slowly progressed for thirty years, resulting in diversion of water traffic to rail.

3. That the dimensions and route of the proposed extension should be examined into and decided by a competent board of engineers, with means and authority to make such additional surveys as their proper enlightenment demands. The expenses and costs of such a board of the surveys are estimated at $30,000; if detailed plans, etc., are to be made, at $75,000.

2206 The locality embraces an important commercial route between the Great Lakes and the Mississippi River system, and its utility and worthiness has long been recognized by Congress.

Preliminary estimates of cost on various plans have been heretofore made, and reports containing them are referred to hereinbefore.

Very respectfully, your obedient servant,

W. L. MARSHALL,
Major, Corps of Engineers.

Brig. Gen. W. P. CRAIGHILL,
Chief of Engineers, U. S. A.

(Through the Division Engineer.)
(First indorsement.)
U. S. Engineer Office,
Northwest Division,

New York, February 20, 1897.

Respectfully forwarded to the Chief of Engineers, United States Army.

I am of the opinion that the upper Illinois and lower Des Plaines rivers are worthy of improvement with a view to extension of navigation from Illinois River to Lake Michigan at or near Chicago.

HENRY M. ROBERT,
Colonel, Corps of Engineers, Division Engineer."

On March 17, 1900, a Board of three Engineers appointed by the Secretary of War, under the Rivers & Harbors Act of March 3, 1899, made a report, which report is in part as follows. Chief of Engineers Report of 1900, Appendix MM., p. 3858. (Rec. Vol. IV, p. 2183.)

"*Extract from a Report of Board of Engineers March 17, 1900.*

Appendix MM of Report of Chief of Engineers 1900.
Page 3858.

Having considered the available facts bearing upon the questions presented, the Board has the honor to submit the following preliminary report, in compliance with Department letter of February 13, 1900.

2184 The instructions of the Board are found in the act of Congress approved March 3, 1899, as follows:

> 'The Secretary of War is directed to appoint a board of three engineers, which board shall make a survey and estimates of cost for the improvement of the Upper Illinois River and Lower Des Plaines River, in Illinois, with a view to the extension of navigation from the Illinois River to Lake Michigan at or near Chicago; said board of engineers shall report the estimates of cost for a channel seven feet deep, and also for a channel eight feet deep, throughout said proposed route; said survey and estimates of cost shall be made in pursuance of and according to the recommendations in report of January twenty-seventh, eighteen hundred and ninety-seven, and there is hereby appropriated for the expenses of said board and such survey the sum of thirty thousand dollars, or so much thereof as may be necessary.'

The report of January 27, 1897, is a 'Preliminary examination of Upper Illinois River and Lower Des Plaines River, Illinois, with a view to extension of navigation from Illinois River to Lake Michigan at or near Chicago,' made by Maj. W. L. Marshall, Corps of Engineers, U. S. A., and published in the report of Chief of Engineers, 1897, pages 2882-2887.

Detailed reports and surveys have also been submitted to Congress by the following officers:

Gen. J. H. Wilson, 1867, report published in House Ex. Doc. No. 16, Fortieth Congress, first session.

Col. J. N. Macomb, Corps of Engineers, Report of Chief of Engineers, 1875, Vol. II, page 525.

Maj. W. H. H. Benyaurd, Corps of Engineers, Report Chief of Engineers, 1884, page 1958.

Board of Engineers on Hennepin Canal and Illinois and Michigan Canal, Report of Chief of Engineers, 1887, page 2125.

Capt. W. L. Marshall, Corps of Engineers, Report of Chief of Engineers, 1890, page 2419.

The last report covers most thoroughly the entire subject, as far as it had then been developed, considers the various routes, shows the character and location of the works required on each, with detailed estimates of cost, and the 8-foot channel of those estimates is a water-way of so nearly the same dimensions as the 7 and 8-foot chan-

nels now called for that the work of the Board might be confined to the presentation of revised plans and estimates derived from this report, if it were not for the
2185 change in conditions which has resulted from the construction by the Sanitary District of Chicago of a drainage canal through the divide between Chicago and Lockport. This channel opens a waterway over this part of the route which more than meets the requirements of the one called for or of any other likely to be called for by those interested in navigation.

If the route by the Chicago River and drainage canal be adopted, there remains but little more than half of the work involved in the 8-foot project of 1890 for the Government now to take in hand in order to complete the improvement, since the estimated cost of this portion of the channel (about 28 miles) was nearly $14,000,000. By the Calumet and Sag route only about 10½ miles of the drainage canal can be utilized.
